OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION

1903-1904

GENERAL OFFICERS

PRESIDENT—FRANK BILLINGS - - - - - - - - 100 State St., Chicago

PRESIDENT-ELECT—JOHN H. MUSSER - - - - - 1927 Chestnut St., Philadelphia

FIRST VICE-PRESIDENT—G. C. SAVAGE - - - - - - - - - Nashville, Tenn.

SECOND VICE-PRESIDENT—ISADORE DYER - - - - - - - - - New Orleans

THIRD VICE-PRESIDENT—C. LESTER HALL - - - - - - - Kansas City, Mo.

FOURTH VICE-PRESIDENT—GEORGE F. JENKINS - - - - - - - - Keokuk, Iowa

SECRETARY-EDITOR—GEORGE H. SIMMONS - - - - - 103 Dearborn Ave., Chicago.

TREASURER—HENRY P. NEWMAN - - - - - - - - - - - Chicago

CHAIRMAN COMMITTEE OF ARRANGEMENTS—B. C. PENNINGTON - - Atlantic City, N. J.

BOARD OF TRUSTEES.

W. W. Grant, Denver, 1904.
John F. Fulton, St. Paul, Minn., 1904.
T. J. Happel, Chairman, Trenton, Tenn., 1904.
E. E. Montgomery, Secretary, Philadelphia, 1905.
H. L. E. Johnson, Washington, D. C., 1905.
A. L. Wright, Carroll, Iowa, 1905.
William H. Welch, Baltimore, 1906.
Miles F. Porter, Ft. Wayne, Ind., 1906.
M. L. Harris, Chicago, 1906.

JUDICIAL COUNCIL.

Term expires 1904: T. C. Martin, Ohio; J. B. Roberts, Pennsylvania; Christopher Tompkins, Virginia.

Term expires 1905: Philip Marvel (Chairman), New Jersey; George Cook, New Hampshire; N. S. Davis, Jr., Illinois.

Term expires 1906: F. H. Wiggin (Secretary), New York; G. B. Gillespie, Tennessee; D. C. Peyton, Indiana.

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, Alexander Lambert, New York; Secretary, J. L. Miller, Chicago. Executive Committee—J. M. Anders, Philadelphia; Frank A. Jones, Memphis, Tenn.; W. S. Thayer, Baltimore.

OBSTETRICS AND DISEASES OF WOMEN—Chairman, L. H. Dunning, Indianapolis; Secretary, C. L. Bonifield, Cincinnati, Ohio. Executive Committee—Henry P. Newman, Chicago; J. H. Carstens, Detroit, Mich.; A. Palmer Dudley, New York City.

SURGERY AND ANATOMY—Chairman, Charles A. Powers, Denver, Colo.; Secretary, E. Wyllys Andrews, Chicago. Executive Committee—A. J. Ochsner, Chicago; DeForest Willard, Philadelphia; James E. Moore, Minneapolis.

HYGIENE AND SANITARY SCIENCE—Chairman, G. T. Swarts, Providence, R. I.; Secretary, J. S. Fulton, Baltimore, Md. Executive Committee—Arthur R. Reynolds, Chicago; H. M. Bracken, Minneapolis, Minn.

OPHTHALMOLOGY—Chairman, R. L. Randolph, Baltimore, Md.; Secretary, Albert E. Bulson, Jr., Ft. Wayne, Ind. Executive Committee—J. A. Lippincott, Pittsburg, Pa.; Frank Allport, Chicago; John E. Weeks, New York City.

DISEASES OF CHILDREN—Chairman, Charles G. Kerley, New York; Secretary, C. F. Wahrer, Ft. Madison, Iowa. Executive Committee—Samuel W. Kelley, Cleveland; H. M. McClanahan, Omaha; John C. Cook, Chicago.

STOMATOLOGY—Chairman, G. F. Eames, Boston; Secretary, Eugene S. Talbot, Chicago. Executive Committee—R. R. Andrews, Cambridge, Mass.; A. H. Peck, Chicago; M. L. Rhein, New York.

NERVOUS AND MENTAL DISEASES—Chairman, F. Savary Pearce, Philadelphia; Secretary, David I. Wolfstein, Cincinnati. Executive Committee—H. A. Tomlinson, St. Peter, Minn.; Richard Dewey, Wauwatosa, Wis.; F. W. Langdon, Cincinnati.

CUTANEOUS MEDICINE AND SURGERY—Chairman, Henry G. Anthony, Chicago; Secretary, R. R. Campbell, Chicago. Executive Committee—W. L. Baum, Chicago; Henry W. Stelwagon, Philadelphia; John A. Fordyce, New York.

LARYNGOLOGY AND OTOLOGY—Chairman, J. F. Barnhill, Indianapolis; Secretary, Otto T. Freer, Chicago. Executive Committee—J. N. Mackenzie, Baltimore; G. Hudson Makuen, Philadelphia; Geo. L. Richards, Fall River, Mass.

MATERIA MEDICA, PHARMACY AND THERAPEUTICS—Chairman, O. T. Osborne, New Haven, Conn.; Secretary, C. S. N. Hallberg, Chicago. Executive Committee—N. S. Davis, Jr., Chicago; George F. Butler, Alma, Mich.; Solomon Solis-Cohen, Philadelphia.

PATHOLOGY AND PHYSIOLOGY—Chairman, Joseph McFarland, Philadelphia; Secretary, Henry A. Christian, Boston. Executive Committee—L. Hektoen, Chicago; Frank B. Wynn, Indianapolis; Victor C. Vaughan, Ann Arbor, Mich.

A CONTRIBUTION TO THE SUBJECT OF RADIOTHERAPY AND PHOTOTHERAPY IN CARCINOMA, TUBERCULOSIS AND OTHER DISEASES OF THE SKIN.*

DRS. JAMES NEVINS HYDE, FRANK HUGH MONTGOMERY AND OLIVER S. ORMSBY.

CHICAGO.

Since 1894, when Finsen published his first paper on the value of the actinic rays in variola, and the year 1895, when Roentgen presented his historical paper to the Physico-Medical Society of Wurzburg, the literature of the general subject of radiotherapy and phototherapy has accumulated in geometric proportions. It is not the purpose of the present paper to survey this literature, but merely to present the results of our personal observations and experience in the management of cutaneous diseases by the modern method of light treatment. It is worthy of note, however, that while the present therapeutic use of the *x*-rays was first suggested as a result of accidents occurring in its use for diagnostic and other purposes, the light-treatment of Finsen and his followers is largely the direct and logical outcome of the work of earlier observers, who studied the influence of light in its various forms on certain phases of animal life.

Recent writers on the subject of phototherapy have made frequent references to the earlier work of (1) Averroës, Black, Waters, Barlow and others on the exclusion of light in the treatment of smallpox; (2) of Unna, Widmark and Hammer on the production of dermatitis and pigmentation by the chemical (violet) rays, and (3) of Duclaux, Downes and Blunt and others on the bactericidal influence of sunlight. Occasional mention is found, also, of the experiments of Graber, Dubois, Bert, Lubbock and others showing an influence of white light and of the violet rays on the movements of certain animals; but the broader and more fundamental researches in this field by Von Sachs and Jacques Loeb have apparently been overlooked by medical writers. It is a matter of common observation that certain plants when left in a room lighter from one side only incline toward the source of light. Sachs[1] demonstrated that in plants lighted from one side only radial structures (stems and roots) bend until their long axes are parallel to the rays of light, and that dorsiventral structures (such as leaves) assume a position in which their surfaces are perpendicular to the light rays. Plants (or organs) which turned toward the light Sachs termed positively heliotropic, and those which turned from the light negatively heliotropic. He demonstrated the three following laws: (1) The orientation of a plant toward (or from) the source of light is determined by the direction of the rays. (2) Only the more refrangible rays (blue and violet) affect the orientation of plants. (3) Light of constant intensity acts continuously as a source of stimulation.

Jacques Loeb,[2] as the result of a large number of varied and carefully controlled experiments on nearly one hundred varieties of animals (including caterpillars, butterflies, plant lice, ants, fly larvæ, various hydroids, the larvæ of beetles, etc.), demonstrated an animal heliotropism which agrees with and conforms to Sach's laws for the heliotropism of plants. Loeb's experiments showed that certain animals when exposed to white light or to blue and violet rays from a single source exhibited the following phenomena: (1) They arranged themselves with their long axis parallel with the rays of light; that is, so that the rays fell at equal angles on symmetrical areas of the body. (2) The animals, if positively heliotropic, moved in the direction of the rays until as near as possible to the source of light, and remained there as long as the light did not fall below a minimum intensity, even though in following this course they passed from a lighter to a darker place. Negatively heliotropic animals obeyed the same law, but moved as far as possible from the source of light. In all his experiments Loeb recognized and carefully controlled all other factors, such as temperature, oxygen supply, geotropism and contact irritability, which might influence the movements of the animals. He experimented with headless animals and with those having no associating cerebral organs, and succeeded in making certain animals positively or negatively heliotropic at will, thus demonstrating that the movements were due not to a subjective sense or "intuition," but to direct stimulation of the muscles by the more refrangible (blue and violet) rays of light. The more nearly the angle at which the rays struck the surface approached a right angle the greater the stimulation; hence, orientation of the animal in the direction of the rays took place before the movement to or from the source of light. These experi-

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. W. T. Corlett, L. Duncan Bulkley and W. L. Baum. The records for the three following months of Cases 9, 10, 11, 13 and 15 have been included, in order to illustrate the danger of producing metastases and extension of the growth when treating carcinoma by radiotherapy, results not definitely presented in reading an abstract of the paper and consequently not discussed at the meeting.

2. "Der Heliotropismus der Thiere und Seine Uebereinstimmung mit dem Heliotropismus der Pflanzen." Würzburg, 1890.

ments show conclusively that the blue and violet light rays are directly stimulating to animal cells. The stimulus results probably from chemical changes, the exact nature of which is undetermined.

Recognizing the importance of Loeb's work, Benedict Friedlander[3] demonstrated by means of control experiments that the dermatitis and pigmentation resulting from exposure of the skin to sunlight, or to strong electric light, are produced wholly by the blue and violet (and not by the heat) rays. He thus confirmed the deductions drawn by Unna, Widmark and Hammer from their observations of sunburn and pigmentation in Arctic explorers and Alpine tourists. Friedlander suggested employment of the arc-light for therapeutic purposes.[4] The later development of a practical light-therapy by Finsen is a familiar subject to all readers of medical literature.

We shall not attempt a complete description of *x*-ray technic, as the subject is considered fully and in detail in the paper of Dr. Louis Schmidt. We use a current from induction coils having a voltage of from 10 to 12, and an amperage of from 1½ to 3 (rarely 4 or 5). The distance from the anticathode of the lesion exposed to the *x*-rays varies from 5 to 15 inches; the duration of the treatment from 3 to 10 minutes; the interruption from 800 to 1,200. For all superficial lesions a medium soft tube, for deeper tissues a moderately hard tube is used.[5] To protect the patient lead plates are employed. As a matter of convenience and for the better protection of the tissue immediately about the area treated we have been in the habit of exposing the latter through an opening in a small disc of lead, which can be closely fitted to the surface and fastened by means of pieces of tape or adhesive strips. A much larger flat sheet of lead, with an opening smaller than the area covered by the first lead disc, is supported by an adjustable rest between the patient and the tube. Each lesion treated has its individual small disc of lead, while the larger sheet answers for a number of areas of about the same size in the same or different patients. For treatment of lesions on the head this part is supported by a photographer's head-rest. By taking these precautions the action of the rays is limited as closely as possible to the part to be treated.

The subject of technic should not be dismissed without consideration of the susceptibility of different individuals to radiotherapy. Some recent writers state that there is no personal idiosyncrasy to the *x*-rays. The truth of such a positive statement is not demonstrable. We believe in personal idiosyncrasy to the *x*-rays, not only as a result of our experience with radiotherapy, but also because to no other therapeutic agent which we employ either internally or externally do all patients respond in the same manner or to the same degree. Every physician who treats cutaneous diseases knows that the skins of different individuals vary greatly in their susceptibility to the action of remedies and other influences, and that not infrequently a patient is found in whom a given remedy produces effects on the skin strikingly different in character or degree from that produced in the majority of individuals. For example, the effect of the sun's rays of a given intensity and duration varies greatly in different individuals, producing in one a slight pigmentation, in another an erythema, and in yet others a dermatitis of varying degrees of intensity. Occasionally an individual is found whose skin is so sensitive to the action of light that the slightest exposure to direct sunlight is followed by the formation of bullæ, small areas of necrosis and scars.

While it is undoubtedly true that in the past many of the untoward effects and the uncertain results obtained from the use of the *x*-rays have been due more to a lack of accurate technic (and possibly of skill on the part of the operator) than to personal idiosyncrasies, we are satisfied that different individuals vary markedly in the manner and degree in which they respond to this treatment. It is unquestionably true, also, that even the most skilled operator is unable, with our present knowledge, to determine with absolute precision the intensity and other qualities of the radiation employed by him in a given case. In other words, it is practically impossible so to regulate all the elements that two succeeding treatments shall have precisely the same value. Until we are better able to control all these elements, it will be a matter of conjecture as to how far the differing results may be due to variation of technic and how far to the readiness with which the patient responds to the treatment. Consequently, whether our variability in results be due to the uncertain susceptibility of the patient, or to the impossibility of regulating absolutely the value of each treatment, *the important fact remains that the only safe guide at present is the reaction obtained in each case.* The treatment in each case, therefore, must be begun gradually and pursued cautiously, and, as a rule, be suspended temporarily at the first indication of erythema or pigmentation. All experienced operators have learned that the effects of the radiation, as evidenced either in the production of a deep-seated dermatitis or in a progressive involution of the lesion treated, may continue for weeks or months after the last exposure to the rays.

Our interest in phototherapy was greatly stimulated by two visits made by one of us to Finsen's Light Institute in Copenhagen, where the opportunity was offered of making a careful examination, not only of the apparatus there employed, but also of patients in all stages of treatment and progress, including those actually relieved of their disease. There was also a large photographic collection showing the condition of patients before beginning and after treatment. A remarkable exhibition of patients and photographs at the International Congress of Dermatology in Paris in the year 1900 served as a further stimulus to the study of this subject. In phototherapy we use Sequeira's modification of the Finsen light. In it the carbons of the arc-light are brought within two or three inches of the area to be treated. Ten or fifteen minutes' exposure thus produces as much reaction as an hour's exposure by the original Finsen apparatus. The patient is protected from the light by a hollow shield, in the center of which are two rock-crystal lenses, front and back, between which cold water constantly circulates and absorbs all heat rays. The part to be treated is rendered anemic by pressing it firmly on the face of the front lens. The reaction after treatment with the lamp occurs in from six to twenty-four hours, and may vary in degree from an erythema to a vesicular or bullous dermatitis. No inflammation of tissue deeper than the skin is produced. The induced inflammation usually

subsides in from three to ten days. In normal skin the reaction is followed by pigmentation, which acts as a protection against the light-rays, so that in a given area successive treatments are followed by a constantly diminishing intensity of reaction. In morbid tissue, the protective pigment is much less marked or entirely absent. In effect the light from the lamp differs, then, decidedly, from the *x*-rays in the following particulars: Reaction occurs promptly; it is always superficial; it leaves a pigmentation, which protects to a degree against the light in successive exposures; and the final results of treatment are apparent usually within a short period of time. With the *x*-rays the reaction is much slower in appearing, from one to two, or even three weeks; it frequently involves deeper tissue; the normal integument once the seat of distinct reaction is usually much more sensitive to subsequent exposure; and, finally, the effects of the radiation are frequently prolonged through several months after the last exposure.

CARCINOMA.

Of 55 cases of carcinoma of the skin treated by us with radiotherapy, the majority were of the superficial type, known generally as epithelioma or rodent ulcer. The value of the *x*-rays in the removal of such growths is so generally recognized that we shall give here a summary merely of our observations, together with brief outlines of a few typical and otherwise interesting cases. In the most superficial forms of carcinoma our results have been quite uniformly successful. As a rule, after giving the lesion a few short exposures and waiting for a period of ten days or two weeks to allow for any unusual susceptibility on the part of the patient to manifest itself, from twelve to twenty-one treatments with a moderately soft tube were given on every alternate day or daily until there appeared a slight erythema, on the recognition of which treatment was suspended, at least temporarily. In discharging ulcers the secretion became markedly less or disappeared in from four to eight days after beginning treatment, while pain or other anomalous sensations usually subsided earlier. All evidences of reaction disappeared, as a rule, in from two to four weeks after the last treatment, leaving in the majority of these cases a soft, inconspicuous scar. In a number of cases, however, in which infiltration extended somewhat deeper, it was found that while the major part of the growth had disappeared, there remained, even after several weeks, a few isolated or possibly a row of epithelial pearls or nodules, which required a second period of treatment similar to but shorter than the first. The cartilage-like border seen in some cases of superficial carcinoma does not, as a rule, yield readily to the influence of the rays, and better and more prompt results can be obtained, we believe, by removing such borders with the curette before resorting to radiotherapy.

In 25 cases (of which Cases 1 to 8 will serve as types) the lesions have been entirely replaced by scar tissue, and there has been no evidence of recurrence during periods varying from two to nine months. Of these patients one only was under 30 years of age; 21 were 40 or older. The age of the lesion was from one to 20 years. The number of treatments given varied from 10 to 27 and were given during a period of time varying from 12 days to 6 weeks. The reaction subsided, together with the disappearance of the lesion, in from 10 days to 4 weeks after suspension of treatment.

In the treatment of surface carcinoma involving the deeper tissue, our results have not been so uniformly satisfactory. In some of these cases the treatment with moderately hard tubes was carried to the point of producing a decided inflammatory reaction in the morbid tissue. While the treatment has been followed in a number of instances by complete disappearance of the tumor, in a few cases the induced inflammation apparently hastened extension of the growth or the formation of metastases. Cases 9, 10, 11, 13 and 15 illustrate very well the rapid extension of the growth following cessation of treatment or the occurrence of metastases during treatment. We have seen, not only in our own cases here reported, but in several cases treated by others, the usual swelling and reaction produced by successive treatments followed by an almost complete disappearance of the growth with the subsidence of reaction, and then, after a few weeks of further rest, a very rapid extension of the growth to the neighboring tissue, producing in several instances, within two or three weeks' time, a larger tumor than that for which the patient was originally treated. In each of these cases the second growth of the tumor has been far more rapid than anything we have ever seen in unmolested carcinoma. The second growth in each instance has had all the clinical features of true carcinoma. In one case, concerning which there was some doubt in our minds, sections of tissue removed from this rapidly extending second growth showed it to be typical carcinoma. In two instances (Cases 10 and 13) and probably in a third (Case 9) metastases have occurred during the successful treatment of the primary tumors. While we are not in position to demonstrate absolutely the pathologic conditions underlying these clinical phenomena, it certainly seems reasonable to suppose that the production of an inflammation in and about the morbid growth must favor the dislodgement and dissemination into surrounding tissues of the carcinoma cells and their transportation by the lymphatics to more distant regions of the body. As the normal tissue immediately about the tumor participates in the inflammation, and has come to some extent under the influence of the *x*-rays, there is produced a zone of lessened resistance, which must also favor extension of the growth. Though the effect of radiotherapy is to produce destruction and degeneration of the carcinoma-cells, is it not possible or even probable that some of these dislodged cells may have so far escaped the influence of the rays that they are still capable of proliferation and of starting a new growth? In attacking these tumors with the *x*-rays so vigorously as to produce in them a marked inflammatory reaction, we believe there is distinct danger of encouraging extension of the growth in surrounding tissues and of producing metastases. Many carcinomas can be removed more slowly by less vigorous application of the *x*-rays. In inoperable cancer, which threatens to be rapidly destructive, experience may yet prove that to attack very vigorously with high-tension tubes, and risk the danger of a deep burn in hope of quickly destroying the tumor, may be a safer procedure than to produce a moderate reaction, which may be followed by extension of the growth.

TUBERCULOSIS.

Our observations have included 14 cases of cutaneous tuberculosis. Of 7 cases of lupus vulgaris, 2 (Cases 17 and 18) have completely recovered; 2 more are nearly well, and the remaining 3 are much improved. In 3 cases involving both sides of the face, phototherapy was used on one side, while radiotherapy was used on the other. In one of these complete recovery occurred on

both sides in practically the same length of time (Case 18). In the second, which was an extensive case of nodular lupus, involving the major portion of both cheeks, the entire nose, the eyelids and a part of the forehead, and was of fourteen years' duration, the two sides have progressed about equally towards recovery. The third, a case similar in type and distribution to the second, but occurring in a child and of only five years' duration, has been under treatment for but a short time.

With phototherapy the best results are obtained when a marked reaction is induced and sufficient time allowed between treatments of a given area for completion of desquamation. The process is necessarily tedious, but the final results are attained as rapidly and are more satisfactory than with other methods of treatment. Two cases made complete recovery in three months, while the second case above described has had continuous treatment for a period of six months. For mucous membranes and places not readily accessible, radiotherapy is advised; but on all accessible places, and especially if not too extensive, phototherapy is preferable, as it apparently requires no more time than does radiotherapy and is free from the danger of producing a more destructive inflammation than is required.

A tubercular ulcer of one year's duration, involving the dorsum of the hand, disappeared completely after eleven treatments with radiotherapy. Two cases of disseminated tuberculosis of the skin having a generalized distribution are gradually being relieved. A case of tuberculosis verrucosa cutis, involving the forearm quite extensively, was greatly improved after seven treatments with radiotherapy. For five months the patient has been unable to leave work long enough to come for further treatment, but reports that the arm is much better than when last examined by us.

In an extensive lupus of twenty-nine years' duration, in which healing with dense and irregular scar-formation had occurred, a carcinomatous growth began to develop two years ago. It was located on and beneath the chin, and was about two inches in diameter, markedly elevated, indurated, and covered with small, wart-like projections. This lesion has received thirty treatments with the *x*-rays during a period of ten weeks, and now shows only a small ulcer level with the cutaneous surface. The patient is the victim of general tuberculosis.

A case of tuberculosis verrucosa cutis of the palm disappeared after fifteen treatments with phototherapy, leaving at present a few small points of hyperkeratosis. In a girl of 17 years multiple tubercular ulcers and sinuses, following the breaking down of tubercular glands, healed completely in ten weeks under the influence of the *x*-rays. The disease began in this case ten years ago as a tubercular dactylitis. The gradual extension of the disease, involving bones and joints, necessitated amputation first above the wrist, and later above the elbow. At the time the patient came to us the axillary glands were involved, and the stump of the upper arm was riddled with tubercular ulcers and sinuses. Amputation at the shoulder joint had been advised by her physician and consulting surgeon. Not only did the ulcers heal under the influence of the *x*-rays, but the enlargement of axillary glands has almost entirely disappeared and the girl's general health has greatly improved.

LUPUS ERYTHEMATOSUS.

In nine cases treated long enough and with sufficient regularity to note results, we found the treatment to be of undoubted value. With one exception, our results have been much better with phototherapy than with radiotherapy, though both methods were tried in several cases. The lesions treated were on the face, nose, eyelids, forehead, and ears, and were of from one and one-half to five years' duration. The usual procedure is to treat one area, one inch in diameter, at each sitting of fifteen minutes' duration. Intervals between treatments for each area vary from five to fourteen days. About two to four hours after treatment some anomalous sensations, such as pricking or stinging, usually occur. In from four to eight hours an erythema usually develops, and in from twelve to twenty-four hours a dermatitis follows, which varies in intensity up to the formation of bullæ. After three or four days the reaction usually subsides with desquamation, and by the end of a week or ten days the process can be repeated. When the lesion is unusually sensitive, it is given protective treatment. Subsequent reactions, as a rule, are not so severe as the first. Lesions in which the vascular element predominates yield most readily, some of them disappearing after two treatments. Cases in which the sebaceous element is marked are more obstinate.

PSORIASIS.

We have treated thirty-two cases of psoriasis with radiotherapy, causing in each case at least a temporary disappearance of the lesions. From four to ten treatments on a given group of lesions were usually sufficient to cause them to disappear entirely, except for a certain amount of pigment. In lesions in which the thickening was but moderate the scales often disappeared after the second or third treatment. Relief from itching when such is present occurs about the same time. As a rule, the first effects noted on a psoriatic lesion are the inability to demonstrate bleeding points and the lessened quantity of scales, which are more readily detached, and lose their micaceous appearance, becoming more friable or even powdery. In about 50 per cent. of the cases new lesions returned, either at the site of the old ones or elsewhere, within a few weeks. Of the remaining cases, both local and generalized, recurrence was delayed in many for several months. In two cases, in which circumscribed areas of psoriasis had persisted for many years in defiance of all treatment, ten exposures were followed by complete disappearance of the lesions, which have not returned after a period of eight months. In a few of the generalized cases, however, it happened that even though the treatment was continued through several weeks, as new regions were treated new lesions would appear on other parts of the body from which the disease had been removed previously. As a rule, recurring patches are removed with fewer treatments than are required for the original ones. It is also true that lesions of short duration are less resistant than those of longer standing. In a single case in which the disease was unusually acute and the skin of the patient especially sensitive, the treatment seemed to render the skin more irritable.

In the treatment of psoriasis we use a fairly soft tube, and very short exposures, at a distance of ten or twelve inches. It has not been necessary in any case to produce any visible evidences of reaction, not even an erythema or pigmentation. The influence of the *x*-rays on psoriasis is in keeping with the fact demonstrated by one of us (Hyde) twelve years ago and frequently since, that some psoriatic patients can free their skins of all lesions by prolonged sun baths.

OTHER DISEASES.

In nine cases of hypertrichosis treated by us with the *x*-rays the hairs were removed in from sixteen to twenty treatments on a given area. In five there was a return at the end of six weeks or two months of a considerable portion of the hairs. In one of these five cases the hairs which returned were removed in nine treatments. After another period of two months a few hairs are again returning. Four of the nine cases have never reported after the first removal of the hair.

In eighteen cases of alopecia areata treated by phototherapy, prompt return of the hair occurred in two, marked improvement in three, and but little or no change in thirteen cases. The treatment does not seem to present any marked advantages over other methods in vogue. We have not used the *x*-rays for fear of producing permanent alopecia, but have used phototherapy to the extent of producing a vesicular dermatitis.

In ringworm of the scalp we have had no success whatever; but here again we have feared to use the *x*-rays freely for fear of producing permanent alopecia.

In a few cases of acne and rosacea our use of the *x*-rays has been followed by very marked improvement. In two extensive and very severe cases of acne, which had resisted for months all our efforts at treatment, the eruptive symptoms disappeared completely under the use of the *x*-rays. In other cases a few exposures have seemed to materially aid the other treatment employed. The cases of acne in which radiotherapy is of unquestioned value are those in which the disease is limited to a small area. Here the treatment may be pushed, if necessary, to the point of producing atrophy of the affected glands and follicles. When many scattered glands are involved and new lesions are constantly forming, radiotherapy gives temporary benefit, but can not be expected to prevent recurrence of the lesions unless the treatment be carried far enough to produce general atrophy of the sebaceous glands of the face. But the sebaceous glands have a function to perform, and to produce a general atrophy of these glands of the face must be a questionable procedure until we can determine what effect such a course would have on the skin ten, twenty, or forty years later. Again, no local treatment can be expected to replace entirely treatment of the underlying conditions on which many cases of acne depend.

In several cases of sycosis we have used radiotherapy with decided benefit. Here again we have reserved the treatment for the few cases that have not responded to older methods, for fear of producing permanent loss of hair.

In a few cases of rosacea and in several instances of fine telangiectases, phototherapy has given good results.

In five cases of keloid-like scars following burns, a series of exposures to the *x*-rays has been followed by a decided softening and thinning, but not by complete disappearance of the scar. In these cases treatment was carried to the point of producing erythema and desquamation; in one only to the point of producing a dermatitis.

In several areas of chronic eczema and in three severe cases of intertrigo radiotherapy has given excellent results. In one exceedingly stubborn case of eczema of the scrotum, of many years' duration, in which a vitiliginous condition had appeared on the infiltrated skin, ten daily treatments gave the patient relief from itching; the infiltration gradually disappeared, and later the normal pigment returned.

In two cases of cutaneous blastomycosis which had refused to heal entirely under the iodid of potassium, the persisting borders disappeared after twelve and sixteen treatments respectively with radiotherapy.

In a case of mycosis fungoides, in which the patient's body was more than half covered with characteristic thickened and scaling areas, some of which were approaching the tumor stage, all lesions treated with radiotherapy faded decidedly or disappeared entirely, while those not so treated remained or increased in size.

Several cases of hyperkeratosis (see Figs. 29 and 30, Case 19) and of pre-epitheliomatous lesions yielded to the treatment.

NARRATION OF CASES.

CASE 1.—Mr. R. H., aged 79; carcinoma of the lip. A brother died from a cancer, also beginning on the lip. On examination the middle third of the lower lip was found to be the seat of a typical superficial ulcerating carcinoma of one and one-half years' duration. A horny mass, the size of a coffee bean, extended outward from the border of the growth. During a period of six weeks 21 treatments were given, after which the entire lesion disappeared, leaving only a thin, soft scar. No sign of recurrence six months after treatment.*

CASE 2.—Mrs. B., aged 61; carcinoma of the inner angle of the eye and root of the nose, beginning in 1898. It had been excised and skin-grafted. On examination, a mass of epithelial pearls was found beneath and on the surface of the flap of grafted skin. During three weeks 20 treatments were given, at the end of which time the tumor-mass and induration had disappeared, leaving the area slightly red but quite tender. One month later all evidences of reaction and of the carcinoma had disappeared. Four months have passed with no sign of recurrence.

CASE 3.—Mr. W. F., aged 60; carcinoma of parotid region, of two years' duration (Fig. 27). The lesion was the size of a large hazel nut, having an ulcerating center, an elevated and hard border and was situated on an indurated base. It was assuming a more malignant type, as evidenced by increased rapidity of growth and greater pain. After 18 treatments, during a period of three weeks, the lesion became bluish and slightly swollen. The discharge lessened after the third treatment, and pain ceased entirely after the sixth. Two months after beginning treatment the growth was entirely replaced by a soft and almost invisible scar (Fig. 28).

CASE 4.—Mr. Ch., aged 45; carcinoma of lip of ten years' duration. The lesion presented a superficial ulcer, situated on an indurated base. During a period of four weeks 14 treatments were given, ten days after the last of which the entire lesion had healed. No recurrence after seven months.

CASE 5.—Mr. O. S., aged 76; multiple carcinomata of the trunk of twenty-five years' duration. He had been for twenty years under the almost constant observation and care of two well-known New York surgeons and of an equally well-known dermatologist of that city, by whom he was referred to us. A large number of the growths had been removed from the chest and back by excision, by curettage, or with caustic pastes. On the chest and breast there remained three irregular superficial areas, ulcerating in places, but made up, for the most part, of small nodules and ridges. There were also numerous small scaling and thickened areas (Fig. 1). During a period of six weeks 20 treatments were given, producing a moderate dermatitis. This rapidly subsided except in one place, which healed slowly, requiring twelve weeks for complete recovery. The carcinomatous areas completely cleared up, leaving more or less scar tissue (Fig. 2. Since this photograph was taken the scars have become soft and smooth). No recurrence after six months. The diagnosis was verified by histologic sections.

CASE 6.—Mr. D., aged 35; carcinoma of eyelid. A large part of the border of the right lower eyelid was the seat of an ulcerating carcinomatous growth, which had destroyed the

* With the exception of Cases 9, 10, 11, 13 and 15, these histories were written, June 1, 1902. There have been no other recurrences since that date, and a number of cases reported here as improved, have recovered completely.

glands, the hair follicles and some deeper tissue. During a period of nineteen days 16 treatments were given, the lid being drawn downward and the eyeball protected from the rays. Considerable reaction and swelling occurred, which disappeared in three weeks, leaving only a soft, thin scar. The resulting deformity is so slight that it is not apparent except on careful inspection. The case is of interest chiefly in demonstrating what can be done about the eye, provided sufficient care be taken, with this treatment. No irritation of the eye further than a mild conjunctivitis occurred at any time.

CASE 7.—Mrs. T., aged 51; recurrent carcinoma of forehead of ten years' duration. The growth had recurred after complete excision and presented a large superficially ulcerating and crusting surface (Fig. 14). During a period of four weeks 14 treatments were given. Some erythema occurred, which soon subsided, leaving a smooth, perfectly healed surface. No recurrence after two months.

CASE 8.—Mrs. C., aged 44; carcinoma of the bridge and side of the nose. Began in 1895; was excised in 1896; recurred in March, 1901; curetted in June, and again in August, 1901. Nov. 8, 1901, a characteristic but superficial ulcerating lesion was present. During a period of one month 13 treatments were given, with only a slight reaction, which cleared up one week later, leaving the usual delicate scar. No recurrence at date.

CASE 9.—Mr. A. C. B., aged 55; multiple carcinomata of the face of fifteen years' duration. A large part of the right cheek was involved, beginning immediately in front of the ear, where one of the tumors had been excised one year previously, and extending to the outer canthus of the eye, and downward onto the nose. The lesions were for the most part superficial, in the form of small pearly nodules or ridges, which in places had been replaced by equally small superficial ulcers or atrophic areas. There were three distinct tumors, the largest being the size of a small walnut and located over the malar bone. The second, somewhat smaller (removed for histologic study) was located about one and one-half inches below and internal to the first; while the third, still smaller, was situated about the same distance below, but nearer the ear. His entire face was more or less covered with irregular, thickened, slightly crusted areas of the type known as seborrheal or senile warts (Fig. 15). Sections from the tumor removed showed the typical structure of carcinoma (Fig. 17). From Nov. 13 to Dec. 2, 1901, 12 treatments were given, when erythema appeared and treatment was suspended. Jan. 6, 1902, the largest tumor had more than one-half disappeared, and the lesions on the rest of the face were much diminished. March 17 only a few small areas remained, but the entire region was given 10 treatments up to March 27. About two days later a severe dermatitis, involving especially the scar tissue, appeared and continued for a period of over two months. As this was subsiding a deep-seated subcutaneous growth involving the region slightly in front, beneath, and back of the ear appeared and grew with great rapidity, attaining the size of a small egg in less than four weeks. As this appeared in a region from which one of the carcinomatous tumors had been excised a year before, it is not possible to determine whether it was a recurrence from the old tissue or a metastatic growth. In either event, the growth of this secondary tumor was much more rapid than usually occurs in unmolested carcinoma. This growth was given 11 treatments without apparent beneficial effect, and four weeks later was extirpated by Dr. Bouffleur. It was then found to involve the fifth nerve quite extensively, and occupied the region of the parotid gland, extending down into the superior triangle of the neck. The region of the operation is again being subjected to radiotherapy with the hope of destroying any remaining carcinomatous cells. The original lesions disappeared completely, leaving a soft, smooth scar (Fig. 16).

CASE 10.—Mr. McC., aged 58; carcinoma of the ear. His father died of gastric carcinoma, and his brother is now under treatment by us for deep carcinoma of the neck (Case 14). The tumor began three years ago. For sixteen months an arsenical paste had been applied. When he came under our observation two-thirds of the ear had been destroyed, the stump being indurated, painful, ulcerating and discharging (Fig. 22). He did not wish to submit to an operation, preferring to try radiotherapy. After receiving 18 treatments during a period of five weeks, the growth was very much smaller, and continued to diminish during the three weeks of rest which followed. The reaction subsided in this time, leaving the ear much smaller and the ulcerating surfaces healed but for two or three small openings leading to deeper-seated disease (Fig. 23). Nine daily and fairly vigorous treatments followed and produced a decided inflammation and tumefaction of the ear. At the end of a four weeks' rest the reaction had subsided and the outlook was favorable, when suddenly (the patient, who was in the country at the time, says within ten days) the growth invaded adjacent tissues and became much larger than ever before. A section of tissue from this new growth showed it to be a true carcinoma and not an inflammatory product. Twenty-one treatments were then given, during a period of five weeks, followed by six weeks of rest. During these eleven weeks the tumor has been gradually but very slowly diminishing in size. The surfaces have not healed, however, and the growth is more extensive than when treatment was begun (Fig. 24).*

CASE 11.—Mr. D., aged 47; carcinoma of the lip of eighteen months' duration, which had been treated with pastes. One half of the lower lip was the seat of a deep, destructive, ulcerating, discharging, and painful carcinoma. During a period of ten weeks 32 treatments were given this lesion, more or less regularly. At the twenty-first treatment the growth appeared less indurated and had but little discharge or pain; but a metastatic deep-seated growth appeared on the ramus of the jaw on the same side. This lesion was given 26 treatments. Six weeks after suspension of treatment the tumor of the lip, which had been considerably reduced in size, rapidly involved adjacent tissues until it was a third larger than before beginning the treatment. The metastatic growth had not yielded to the treatment and the patient has consented to a radical operation.

CASE 12.—Mrs. K. B., aged 46; carcinoma of the nose. A superficial, ulcerating lesion of two years' duration was located on the front of the nose, while a deeper-seated tumor of ten years' duration was situated on the side of the nose (Fig. 11). During a period of twelve days the former lesion received 9 treatments, and fourteen days later was replaced by scar-tissue. During a period of ten weeks the tumor received 33 treatments, after which it disappeared, leaving an excavation (Fig. 12) which is slowly filling up. A rim of epithelial papules was left, which received 22 additional treatments, with the result that most of them were removed (Fig. 13). A few more treatments will probably be necessary.

CASE 13.—Mrs. D. B., aged 76. The patient was extremely ignorant and talked but little English or German. The history was unsatisfactory, aside from her statement that the lesions had been present a number of years. A deep-seated, ulcerating and destructive carcinoma involved the entire lower lip (Fig. 9), with metastases in the submaxillary gland of the right side. A superficial, but typical, carcinoma was situated on the left cheek, and there was a large, malignant papilloma on the dorsum of the left hand (Fig. 7). After 12 treatments on the lip and hand, during a period of two weeks, the discharge from the former had ceased; the lesion was smaller (Fig. 10) and the involved gland was much reduced. These treatments were energetic, and the result was a marked dermatitis about both lesions. On its subsidence the tumor on the hand had nearly disappeared (Fig. 8. An unhealed area from the dermatitis shows above the site of the tumor). During the next two months the lip received 19 treatments and continued to improve, the tumor and dermatitis of the hand disappearing entirely. Treatment was temporarily suspended. Three weeks later the patient returned, showing a rapid growth of the right submaxillary gland originally involved and a rapidly growing tumor of the left submaxillary region.

* Extension of the growth continued and the patient finally consented to a radical operation. Dr. A. D. Bevan excised the entire mass and covered the surface with skin grafts, which are growing well and cover all but a small area.

The patient became discouraged and refused further treatment.

CASE 14.—Mr. McC., aged 76; recurrent carcinoma of the neck. His father died of gastric carcinoma, and a brother is reported in Case 10 of this series. The disease was of twelve years' duration; beginning behind the ear, extending downward. It has been extirpated six times. The tumor was entirely subcutaneous, the size of a hen's egg, firmly adherent, hard, painful, and immovable. During three weeks 19 treatments were given; after the tenth treatment deep-seated tenderness and swelling began and increased toward the end of the treatment. Four weeks later the swelling and tenderness disappeared, leaving the tumor smaller and freely movable. During the following two weeks 14 treatments were given; tenderness followed the fourth and swelling began at the fifth treatment. Both of these symptoms were marked when treatment was suspended. Two weeks later the swelling and tenderness are again subsiding.

CASE 15.—Mr. P. D., aged 55; carcinoma of the face. His disease had been treated with pastes. He presented a typical ulcerating carcinoma about one and one-half inches in diameter, involving nearly the entire thickness of the cheek, beginning at the angle of the mouth and extending upward, outward, and downward. He had been subjected to the *x*-ray for three weeks before consulting us. After an interval of rest he was given, during three weeks, 14 treatments, after which a decided reaction led to a rest of three weeks. Some improvement was noted at first, but during the latter half of this second period of rest the tumor rapidly extended and involved the surrounding tissue. During the next three weeks 16 treatments were given, after the ninth of which the spreading ceased and the lesion began to flatten. The treatment was again suspended temporarily because of the reaction, and the growth seems to be at least quiescent, but the loss of normal tissue is much greater than at the commencement of treatment.

CASE 16.—Mrs. A. D., aged 70; superficial carcinoma, of ten years' duration, of forehead, nose and cheek. The involved areas were more or less covered with crusts, epithelial pearls and ridges, small scars, and superficial ulcers (Fig. 31). During a period of six and one-half weeks 22 treatments were given, when slight reaction occurred. A month later all evidences of inflammation and of the original growth had disappeared except for scars and pigmentation and for a small circumscribed area bordered by a few characteristic pearls (Fig. 32). In the two months which have elapsed since the last photograph was taken the pigmentation has disappeared and the scars have become very inconspicuous. The small ulcer has healed, but a few pearls remain and will require further treatment.

CASE 17.—Miss M. J., aged 20; lupus vulgaris. An irregular area, about one and one-half inches in diameter, had existed on the left cheek for twelve years, but by constant treatment and frequent scraping had been kept fairly under control. Tubercle bacilli were demonstrated in the nodules, portions of which inoculated beneath the skin of guinea-pigs, produced in them general tuberculosis. Jan. 18, 1902, a small patch still remained at the lower angle of the original area. This was given 17 treatments with phototherapy during a period of three months, at the end of which time all evidence of the lupus infiltration was absent and the heavy scar tissue left from former treatment was much reduced and softened.

CASE 18.—Mrs. J. L., aged 30; lupus vulgaris of five years' duration. There were three areas on the right cheek and temple (Fig. 20) and one on the left cheek and side of the nose (Fig. 18). The lesions on the left side were given 11 exposures to the *x*-rays during a period of four weeks, beginning Nov. 20, 1901, when some erythema appeared. Beginning again on March 4, 1902, 15 treatments were given during a period of four weeks, when reaction again was manifest. One month later all evidence of the nodules had disappeared, leaving only a delicate scar (Fig. 19). Each of the three areas on the opposite side received, during a period of three months, 8 to 10 treatments with phototherapy, at the end of which time they were also entirely free from nodules and showed only a very thin scar (Fig. 21). Since the last photographs were taken the scars on both sides have smoothed out and become even less conspicuous, the pigmentation having disappeared entirely.

CASE 19.—A. C., aged 5 years; congenital keratodermia of palms and soles (Fig. 29). Both palms and soles were covered with thick, dark brown and almost black horny plates, the thickening of the skin being so marked that complete extension of the fingers was not possible. Treatment with plasters, pastes and ointments produced but slight and temporary improvement. From Jan. 29 to May 22, 1902, 9 radiotherapeutic treatments were given, at the end of which time most of the horny material had been removed and the skin of the hands was much softer and lighter in color, and the fingers could be completely extended (Fig. 30). During the following few weeks 7 more treatments were given the palms, still further improving their condition. It is now two months since the last application was made to the hands, and there has been no return of the original trouble. The same treatment, with similar results, is now being applied to the soles of the feet.

CASE 20.—Mrs. A. C., aged 70; multiple carcinoma of the face, of fourteen years' duration. Midway between the malar eminence and the bridge of the nose on the right side was located a characteristic ulcer, having a raised, hard border and a deeply indurated base (Fig. 5). A similar lesion, but not quite so deep-seated, existed over the left malar bone; while on the right temple there was a large senile wart. During a period of five weeks twenty-seven treatments were given. Seventeen days after suspension of treatment the lesions were swollen and still reacting, but after an additional seventeen days there remained only some pigmentation and a slightly depressed scar (Fig. 6).

CASE 21.—Mr. Br., aged 65; carcinoma of three years' duration, involving the region over the root of the nose, extending to the inner angle of either eye, also some distance on the forehead, and occupying one-half of the left upper eyelid (Fig. 3). Fifty treatments were given at irregular intervals during four months, leaving only a very delicate scar, in which two epithelial papules can still be detected (Fig. 4).

CASE 22.—Mrs. H., aged 45; rodent ulcer of fifteen years' duration, situated back of lower part of the ear. Had recurred from a former operation (Fig. 25). Seventeen treatments were given during a period of four weeks. One month later nothing remained except a fine scar with one small epithelial pearl at the upper angle of former lesion (Fig. 26).

CONCLUSIONS.

While it is too early to form definite and sweeping conclusions regarding the value of radiotherapy and phototherapy in all the affections in which they have been employed, our experience leads us to believe that in tuberculosis of the skin these methods of treatment are superior to any others now known to us. In lupus erythematosus, phototherapy has in our hands given very satisfactory results, far better than those we have obtained by any other method.

In superficial carcinoma involving considerable areas, radiotherapy is undoubtedly preferable to all other known methods of treatment. Superficial lesions more circumscribed are equally amenable to treatment with the *x*-rays, though in many instances small tumors can be removed more promptly by complete erasion or excision. For many of these circumscribed growths we are now inclined to advocate removal either with the knife or curette, followed by a series of treatments with the *x*-rays. In operable carcinoma of the skin which includes deeper tissues, we advocate complete extirpation followed by *x*-ray treatments. Where the growths are inoperable radiotherapy offers a possible chance of recovery, or of lessening the discomfort of the patient. As a result, however, of our observations of our own and other cases, we believe that in exciting an inflammation in carcinoma one is, to some extent at least, en-

couraging an extension of the growth through a dissemination of the cancer-cells to normal (or inflamed) tissue surrounding the growth and of favoring metastases. We believe this possibility constitutes a danger in the treatment of carcinoma by the *x*-rays that has not been sufficiently recognized.

The value of radiotherapy in extensive cases of hypertrichosis has been fairly well established by other observers. It has given us excellent results in the majority of cases of psoriasis treated. It has unquestionably been used successfully in many of the chronic inflammatory diseases of the skin, especially in acne, rosacea, folliculitis, and suppurating wounds; but until this agent can be employed with greater accuracy we believe it should be reserved chiefly for those cases in which better known and better controlled methods are not successful.

It is not yet possible to draw definite conclusions with reference to the comparative values of radiotherapy and phototherapy. The former is, for the most part, readier of application and apparently has a wider field of usefulness than the latter. In lupus erythematosus, however, phototherapy has repeatedly given us excellent results where the *x*-rays have failed altogether or aggravated the condition. Judging from our experience and from the larger experience of Finsen and others in the treatment of tuberculosis of the skin, we believe that in this disease phototherapy gives in the end results as rapid as those obtained with the *x*-rays, with better cosmetic effects and without danger of deep burns.

There is no doubt that both phototherapy and radiotherapy are valuable additions to our methods of treating certain diseases. There is also no doubt that their field of usefulness eventually will be proven much more restricted than that in which they are employed at present. Unfortunately there can be no doubt also that harm is doing and will be done by the action of *x*-rays in the hands of the unskilled or the unscrupulous. No one should attempt to employ radiotherapy who has not first carefully studied the subject and followed the work of some expert. Even with such preparation great caution is needed in acquiring experience with this new therapeutic agent; its accurate control and the character of results obtained being still subjects of discussion.

NOTES ON *X*-RAY TREATMENT OF CANCER,

WITH REPORT OF CASES.*

G. E. PFAHLER, M.D.

ASSISTANT CHIEF RESIDENT PHYSICIAN, PHILADELPHIA HOSPITAL.

PHILADELPHIA.

One year ago the treatment of cancer by means of the Roentgen ray was in an experimental stage. To-day the medical profession seems to recognize it as a valuable therapeutic agent in certain forms of cancer. The successes of the past, however, simply stimulate us to search for new uses and find the best technic to enable us to accomplish these results most quickly and with the least possible danger to the patient. I shall therefore review briefly the histories of a few cases, selecting only those that seem to present some new feature, and then draw conclusions from the results in these particular cases and from observations made by others as well as by myself.

CASE 1.—M. B., white, aged 80. For twelve years had an epithelioma at the base of nose. The size and location is indicated by Fig. 1. Patient was treated with a weak light three months. At the expiration of this time the growth had almost healed. I continued the exposure with the result that the whole surface broke down again. At about this time her general health failed, and I supposed the return of the ulcer was due to low vitality. She was then too weak to be moved and exposures were discontinued. She died three months later of phthisis pulmonalis. At the time of death the entire area had been healed and was covered with a healthy, pink scar (Fig. 2).

CASE 5.—R. F., white, aged 70. Had an epithelioma of the right inner canthus and lower eyelid for five years (Fig. 3). He was exposed to the rays two to three times a week, and improvement was noted until he had 20 exposures. It then seemed to be at a standstill. Treatment was continued with increased vigor until he had 40 exposures. No improvement was noted after the 20th exposure. He then left the hospital and treatment was discontinued. No other treatment followed. Four months later he returned to show me that the area had entirely healed (Fig. 4).

These two cases progressed nicely to a certain stage and then seemed to be failures. In Case 1 I undoubtedly produced an *x*-ray burn, which I mistook for a return of the ulcer. In Case 5 I produced no burn, and yet I must have been keeping up sufficient irritation to destroy the new granulations as they formed. These cases indicate that we may do too much, and that when we reach the stage where the cancer seems to have been destroyed and the process of repair well started we should give Nature a chance.

Fig. 1. Case 1.

CASE 7.—M. M., white, aged 52. Had three operations on the nose during the past three years (prior to admission to this hospital) for the removal of some kind of tumors in the right nostril; the last operation had been performed six weeks prior to admission. She was admitted June 13, 1901, at which time her right nostril was filled with a new growth. July 12, 1901, Dr. E. B. Gleason removed a portion of the growth, which he decided was malignant. Aug. 1, 1901, Dr. Charles P. Grayson removed a portion of the growth, the removal of which was followed by a profuse hemorrhage.

Sept. 4, 1901, the laryngologists refused to treat the case further, and she was transferred to the surgical wards. At

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. W. T. Corlett, L. Duncan Bulkley and W. L. Baum.

this time the growth involved the inner third of the right eyelid, the entire right side of the nose, the antrum of Highmore and the roof of the mouth, at least the soft palate was indurated. The surgeon did not advise operation. A section was removed and referred to Dr. Flexner for pathologic examination. He reported that it was an epithelioma. She was given two exposures, September 7 and 13. Prior to the second exposure she had had constant pain. After the second exposure she volunteered the information that the pain had been relieved. Operation was then reconsidered and *x*-ray treatment was discontinued until Feb. 1, 1902, when she was taking morphin 1/3 gr. for the relief of pain. The entire orbit now seemed to be involved; the nose was swollen and there was distinct bulging of the antrum. She was then given an exposure of ten minutes at a distance of five inches with a vacuum corresponding to a parallel spark-gap of 2½ inches without a shield. After this treatment her pains were relieved and the morphin has been discontinued from that time to the present. Exposures were made every three or four days. After the first exposure a redness of the skin was noticed. After the second the cauliflower growths (about the eyelids) began to round off, and after the sixth had sloughed away. After the fourteenth exposure the skin broke over the antrum sufficiently to allow considerable pus to be discharged. This opening healed very promptly, and to-day (to all appearances) is as well as the opposite side of the face.

Fig. 2. Case 1.—Showing ulcer healed.

Fig. 3. Case 5.

Fig. 4. Case 5.—Four months after treatment had been discontinued showing ulcer healed.

Fig. 5. Case 9.

Since the fourteenth exposure the progress has been slow, but steady. Up to the present time she has had 26 exposures. The right nostril is still about half filled with a growth that seems to be breaking down. The skin over the nose has at no time been broken, but has been kept constantly red. The patient in all likelihood would have been dead ere this without treatment, and the case is one of importance because of the cancer being destroyed beneath the skin.

CASE 9.—D. S., white, aged 72. One brother died from cancer of the cheek. The patient has had a cancerous ulcer affecting the left eye, forehead and face, accompanied by severe pain for 19 years. The extent of growth is shown in Fig. 5. A similar growth had developed at the inner canthus of the right eye and was connected to the larger ulcer by sinuses through the base of nose. There was also an elevated growth on the right chin the size of a silver quarter. Upon admission to this hospital (April 1, 1902) he was too weak to walk—his legs were very

Fig. 6, Case 9.—All cancer tissues apparently destroyed, though not healed—edges healing. Lower portion shows *x*-ray burn.

edematous and he was very cachectic. I felt certain that he would not live long. His complaint of great pain and my anxiety to ascertain what would be the result of *x*-ray treatment in a dying man caused me to commence treatment. He was given five exposures, April 1, 2, 16, 23 and 26. His pains were relieved. After the second exposure Dr. Howard Hansell, at my request, removed the eyeball, which had been extremely

Figure 7.

sensitive. The cancer was exposed ten minutes at each exposure, with a soft tube at a distance of 1½ to 4 inches. A shield was not used at any time on account of the extensive and general involvement. After the last exposure a dermatitis was noticed extending downward on the left cheek. The patient, by this time (after one month), had grown too weak to be moved. He died May 8, when the second photograph (Fig. 6) was taken. By this time the growth on the right chin had disappeared. The large ulcer on the left side showed none of the original characteristics of cancer, and I believe the cancer itself had been destroyed. It had not healed for the reason that time had been too short, but the edges showed distinct signs of healing. The lower portion of the affected part shown in the picture was an *x*-ray burn and not cancer.

Sections were removed from four different parts and sent to the pathologist to determine whether any cancer tissue can be found microscopically. He has not as yet had time to make a report.

I report this case because of the remarkable improvement from five exposures and to show that improvement may occur even with the lowest vitality.

CASE 17.—A. T., aged 73. Had multiple, superficial epithelioma of the skin, varying in size from a pinhead to a quarter dollar. She has had 12 exposures, and all have desquamated but the largest, leaving a red surface.

CASE 18.—R. M., white, aged 94. Has similar multiple epitheliomata, and is improving.

Good results in cutaneous cancers and other diseases of the skin have been reported by Drs. Sequeira,[1] Williams,[2] Rinehart,[3] Taylor,[4] Johnson and Merrill,[5] and others. Most encouraging results have been reported in the treatment of recurrent cancer of the breast by Drs. Hopkins,[6] Clark,[7] Pusey,[8] Soiland,[9] Morton,[10] Scott,[11] Gocht,[12] Despeignes,[13] Stenbeck[14] and others. Only a

Fig. 8.—Cancer apparently destroyed except a small nodule at the outer side.

few have been reported cured, the others are still under treatment and improving. My experience with cancer of the breast is limited to four cases; two were primary, in which operation was refused. One of these had almost entirely healed when death resulted from an attack of uremia. Autopsy showed an indurated gland of the axilla the size of a large pea. The axilla had never been exposed. This teaches that, no matter how superficial a cancer of the breast seems to be, the axilla should be exposed. The other primary case was an old woman, who likewise died of uremia, after four exposures. The cancer apparently had been destroyed, except a small nodule in the upper and outer portion (Figs. 7 and 8).

THE TECHNIC USED.

A brief review at this time of the technic used in this work by myself and others may be of value, though I realize that no rules can ever take the place of experience and good judgment in adapting this energy to the needs of each case.

1. Both the coil used and the static machine give good results, but the balance of favor seems to be with the coil, as producing the quickest results.

2. A low vacuum tube corresponding to an air gap of 1½ inches seems to be universally accepted as the best for all superficial treatment, while for the deeper structures a higher vacuum tube corresponding to an air gap of 3 inches will give better and safer results, Dr. Morton recommends one as high as 7 inches for this purpose.

3. The distance of the tube from the exposed part will vary with the amount of energy and the resistance of the tissue, but seems to be safe at from 12 to 3 inches. Dr. Pusey recommends from 30 to 12 inches. By placing the tube near, however, we save energy and time, and if the tissues are watched carefully, I believe no serious results will follow.

4. The time of exposure should be from 5 to 20 minutes, depending on the reaction obtained, and should be repeated every second or third day, unless some contraindication should arise.

5. The surrounding tissues are best protected by lead foil (a convenient and economical method is the use of tea lead) in one or two layers, which may be covered on both sides by layers of adhesive plaster.

6. Best results, judging from cases reported as well as my own experience, seem to follow when the skin has been brought carefully to a reddened condition and kept so, without producing ulceration. This may occur in 24 hours or not until several days have elapsed after the exposure producing it.

7. I have found that dusting the open surfaces with equal parts of salicylic acid, boric acid and starch helps to keep the ulcer clean and assists in the formation of a cicatrix. Dr. Taylor recommends the use of an ointment of salicylic acid, 10 grains to the ounce of vaselin.

8. The time required to cure a superficial cancer is usually from two to six months. The deeper ones often require longer time.

The results obtained seem to be due to the *x*-ray itself or to a ray that moves in straight lines, similar to the *x*-ray. This point is illustrated by a case which I reported in the *Therapeutic Gazette,* March, 1902.

We can recommend the use of *x*-ray in all carcinomata, but especially those that are inoperable, or in which operation is refused. I would recommend that all cases operated on should be followed by a course of treatment by the *x*-ray. This latter method I believe would bring about the most rapid and successful results.

Bats as Transmitters of Contagion.—Plague broke out in a solitary outlying house near Naples during the recent epidemic. The house had its separate water supply and none of the usual means of contagion could be incriminated, but Gosio noticed that bats were numerous about the place. He experimented to see if bats were susceptible to plague, with positive results. Further experiments with the numerous fleas on the bats showed that they were capable of transmitting the contagion to man. The *Allg. Med. Ct.-Ztg.*, which quotes the results of Gosio's research, observes that this is the first time that the bat has been shown to be harmful to man.

THE TECHNIC OF *X*-RAY THERAPY AS APPLIED TO DISEASES OF THE SKIN.*

LOUIS E. SCHMIDT, M.S., M.D.
Associate Professor of Genito-Urinary Diseases, Chicago Policlinic; Attending Genito-Urinary Surgeon and Dermatologist, Alexian Brothers' Hospital; Clinical Professor of Genito-Urinary Diseases, Northwestern University School of Medicine.
CHICAGO.

Schiff has, within the past twelve months, stated that beginners in this mode of treatment should proceed in a different manner than the more experienced. This statement alone from such an authority shows the unsatisfactory state of affairs. Other writers have attempted to formulate rules, but none have been universally accepted.

THE PREPARATION OF THE PATIENT.

To begin with: how are the surrounding healthy parts of the area to be put under treatment to be protected from the action of the *x*-rays? Rollins devised a box in which the tube is enclosed. This is coated on the inside with heavy lead paint and has a diaphragm of changeable size, so that the size of the cone of *x*-rays passing to the outside may be regulated. This contrivance is used but very little, probably partly on account of its cumbersomeness. As the surrounding healthy parts clearly ought to be protected I find it convenient to make shields of sheet lead. Several thicknesses ought to be on hand for the convenience of bending or plying the metal to the configuration of the body. I have on hand three grades, lead sheeting one-twentieth of an inch in thickness, then tea lead No. 1, and for the thinnest quite heavy lead foil. With the one or the other of these any part, no matter what the irregularities are, may be covered. Each patient ought to have his own shield. The shield, of course, must have a diaphragm through which the rays may reach the diseased parts. It has been recommended that the lead should be underlaid with paraffin paper so as to avoid lead contact. This is a minor point, but is important occasionally on account of contact sparking, as it is a non-conductor. The lead shield is to be held in place by a stand, if possible, and not by the individual. Many observers believe grounding of the shield to be an advantage, but I dare say it is done only exceptionally, and personally I rarely use it. As the large number of cases that come under the treatment of the dermatologist have affections of the face it is desirable to make a perfect-fitting mask. This is readily done by using a manikin.

TRIALS TO DETECT IDIOSYNCRASY.

All patients should undergo a few trial applications previous to any extended course of treatment on account of a possible idiosyncrasy of the patient towards the *x*-rays. This condition is denied by Kienboch and others. Nevertheless, these first carefully observed exposures demonstrate whether or not the individuals react suddenly and severely after such exposures. It is best to even have from five to ten days, or even longer, intervene previous to again taking up the application of the *x*-rays. I have never had such a case of idiosyncrasy. It is best to have the first sitting of ten minutes' duration with a tube of medium penetrating action, as will be described later, and the tube at about a distance of 20 cm., the second treatment given on the fifth to tenth day in the same way at a shorter distance, say 10 to 15 cm., and for at least fifteen minutes.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. W. T. Corlett, L. Duncan Bulkley and W. L. Baum.

I continue to follow this procedure in every case, because no patients are alike and the sensitiveness of each differs, as to the variation of dryness or dampness of the skin, in the acidity or alkalinity of the perspiration, in anemic or plethoric conditions, in electrical resistance.

HOW TO MEASURE THE ENERGY.

Freund and Schiff are usually quoted in the matter of the treatment of skin diseases by the *x*-rays. Their directions are to use a current of 12 volts and not more than 1.5 amperes with a spark length not exceeding 30 cm. and with 800 or 1,000 interruptions per minute.

The ordinary method in use to register the amount of energy going through a Roentgen tube is by stating the amount of amperes and volts or Watts passing through the primary windings of the coil. This method does not measure the amount of the electric energy at the terminals of the secondary coil, but measures the energy at the primary.

The conversion of the amount of electric energy supplied to the primary of an induction coil and the amount received at the terminals of a secondary depends on the design of the induction coil. One make of coil will produce with 1.5 amperes and 12 volts (or 18 Watts) passing through the primary a 20 cm. spark, while another with the same primary energy will only produce a 5 cm. spark. This difference depends on a number of factors, as:

(*a*) On the number of ampere turns of the primary to that of the secondary windings.

(*b*) On the amount of space (air gap), on insulation between the primary and secondary, and also on the insulation of the winding of both coils.

(*c*) On the primary iron core, thickness, length, on number of wires and quality of iron core (magnetic lag).

(*d*) On the number of turns and thickness of the wire of the secondary.

(*e*) On the type of the interruption, whether the primary current is made perfect and broken sharply or otherwise.

In consideration of these facts a statement of amount of amperes and volts passing through the primary gives very little information as to the actual energy passing between the terminals of the secondary. It probably would be quite as correct to state the electrical energy of a static machine by measuring the amount of current passing through the electric motor driving its revolving plates.

Very early after the discovery of the *x*-ray it occurred to many to register the efficiency of an *x*-ray tube by standardizing the degree of *x*-ray light by the penetrating power of its *x*-rays through various dense metals. These consist essentially of varying number of superimposed aluminum plates and then evening them with the aid of a fluoroscope. Luck octinometers or skiameters are somewhat but not extensively used.

HOW TO JUDGE THE STRENGTH OF A TUBE.

As a standard for judging the strength of my tubes, i. e., for measuring the electric energy consumed by any tube, I wish to mention a method which is simple, cheap and that can be used on all coil and static machines or for any electric energy operating an *x*-ray tube. A separate shunt is introduced into the secondary, i. e., parallel to the *x*-ray tube by means of two sliding contact points. If the amount of electric energy is to be measured the points are brought within such a distance of each other that the energy passes between the points of the shunt-spark gap. This method will measure with comparative accuracy the length of the spark in cm. which a tube will consume. This taken in conjunction with a tube of definite size and distance of the terminals with a general statement of its apparent degree of vacuum—soft or hard—will give a fairly correct definition of its power. Of course, the fluoroscope must be used to give us information as another corroborative test, but the former method is of prime importance, because by its use we can prevent an excess of electrical energy passing through and around the tube and thus limiting the power of the tube as much as possible to the production of *x*-ray, with the avoidance of an excess of heat rays and possible sparking around the outer terminals of the tube. In this manner it is possible to find the spark length that the vacuum tube will show its greatest efficiency. It also serves the purpose of demonstrating a soft or a hard tube, provided the size of the tube is taken into consideration. Hence the apparatus, whether with induction coil run with 12 or 110 volts, or even more volts, as in some static machines, makes no essential difference, if the previous mentioned mode of measurement is used.

THE VACUUM AND ITS REGULATION.

Now with the strength of the current measured there are three other important factors to consider:

1. The tube—the vacuum.
2. The position of the anode, and the distance of the tube from the skin.
3. The length of time and frequency of the sittings.

For all practical purposes at present all tubes are of two types:

(*a*) In which the vacuum can be regulated and which may or may not be automatic.

(*b*) In which the vacuum can not be regulated and which are not automatic.

Both types vary as regards size, shape and position and shape of terminals. These conditions are of importance. The tubes which are extensively used are the Gundelach. This has a vacuum which can be regulated. The Mueller tube with vacuum which can be regulated and which besides is automatic. These two tubes will suffice to explain. It will be unnecessary to go into detailed description of them, as they are the tubes in general use.

The second type of tube, the vacuum of which is neither adjustable nor automatic, need not at present be considered, as they are scarcely ever used.

Roentgen, from a physical view, divides all tubes as regards their vacuum either into hard or soft. In the former a more or less perfect vacuum exists than in the latter.

Kienboch divides tubes into five divisions which correspond to the variations of the vacua:

1. Too hard tubes (no light, no *x*-rays).
2. Hard tubes (light, little contrast picture).
3. Medium soft tubes (good, contrast picture).
4. Soft tubes (large quantity of *x*-ray—not penetrating).
5. Too soft tubes (no *x*-ray—electric energy is converted into heat).

Alhers recognizes four divisions. These he establishes by the color of the bones of the hand on the fluorometer:

1. Hard (gray).
2. Medium soft (gray-black).
3. Soft (deep black).
4. Very soft.

The latter two divisions of Kienboch and Alhers are made from a practical standpoint.

It has been stated and it is generally upheld that fairly soft tubes give quicker and more effective results

than hard tubes, although Schiff recommends the latter for our therapeutic uses.

A few axioms in regard to the tubes may be enumerated and may be of value:

With the mode of measurement suggested it holds true that the higher the vacuum the larger the spark (in the shunt). A large quantity of fluorescence does not necessarily mean a large quantity of *x*-rays. It usually means a low vacuum or signifies a fresh tube. It depends on the composition of the glass used (or on the deposit of aluminum on the inner wall of the tube, as in old tubes). It is explained in this manner: In a fresh tube the particles of aluminum have not been deposited on the inner wall of the tube (i. e., not on the light hemispheres). In an old tube where this deposit has taken place there must be a larger amount of current for the same amount of glow, i. e., compared to a fresh tube, because electricity passes over the aluminum surface and passes to the anode. This shows that the glow depends on the amount of bombardment directed on the illuminated hemisphere.

The fluorescence should always be evenly distributed over one-half of the hemisphere. Irregularities, as bright areas, may denote a tube of high vacuum.

RELATION OF HEAT RAYS TO X-RAYS.

Do not use too soft a tube. It may not produce sufficient *x*-rays for the treatment of skin diseases. Suitable *x*-rays can only be produced in tubes of medium vacuum. In a quite low vacuum tube the electric energy is converted into heat rays. The fluorescence of tubes changes by long use, and especially by the use of excessively strong currents.

It is the aim to run a tube at its highest efficiency, i. e., to produce the greatest quantity of *x*-rays from the least current that passes through the tube. An anode that becomes red hot shows that the current in part in these cases is in part converted into heat and not all into *x*-rays. These are not to be used in skin *x*-ray work. In these cases more electricity is being passed through the tube than the vacuum of the tube can convert into *x*-rays. There must be a certain degree of vacuum, otherwise there is no conversion into *x*-rays. To explain: If a high vacuum tube and a 15-inch spark is passed through a terrific amount of *x*-rays is generated. The same spark in low vacuum tube the electricity is partly converted into heat, then the anode disintegrates, and even a puncture of anodal plate may occur—this may then lower the vacuum still more.

THE POSITION OF THE TUBE.

As to the position of the anode and the distance of the tube from the skin. The general consensus of opinion as regards the anodal plates is that the rays are thrown at right angles, i. e., the angle of incidence equals the angle of refraction. There are intratubal poles which vary in shape. Those that are flat are to be preferred; the rounded ones have distinct disadvantages.

The distance of tube is usually 5 to 15 cm., according to the strength of tube used. When enforcing parts beyond this distance the efficiency becomes less, if nearer a more rapid and intense reaction will probably occur. The distance is best measured from the focus of the anode; the size of tube is always stated. Also measured from the tube. My measurements have reference from tube because I mention size of tube, shape of tube and also its spark length and about its vacuum, etc., and it is as accurate as possible. Codman uses to demonstrate this fact the simple law of light or any other energy radiating from a point:

If A is the focal point and 2 twice the distance of 1, then 2 will be four times as large as 1, and the intensity of radiant energy reaching it will be one-fourth as great, i. e., the intensity of the *x*-ray raises inversely as the square of the distance.

Codman has also stated that the danger from burns, like the intensity of *x*-rays, varies directly as the time and inversely as the distance. Furthermore, he has stated that one exposure producing injury has been at a distance of 2.5 cm. for 5 seconds, and another at a distance of 60 cm. for 28 minutes and 48 seconds.

In practice the distance and length of time is constant, but as to the number of sittings of treatment is indeterminable beforehand. Sometimes twice daily or but once and again three times a week may be desirable. Again, the individual sittings may increase to 15 or even 20 minutes' duration. During the early manufacture of *x*-ray tubes the spark gap was utilized to distinguish hard and soft tubes for trade purposes, but latterly some other method is employed.

SUMMARY.

Now, after having considered all these factors: strength of current, tube, the vacuum, position of anode and distance of tube, length of time and frequency of sittings, etc., the dosage may be regulated by (1) increasing or decreasing the *x*-rays, (2) applying them in a more or less intense manner.

The former depends then on the tube used if the efficiency is measured as suggested, and not as to what kind of induction coil or static machine, or with the amount of volts or amperes. The latter condition is fulfilled by either increasing or decreasing the distance at which the tube has its best efficiency for working purposes, and also by the length of the individual and amount of total applications of the rays.

DISCUSSION

ON THE PAPERS OF DRS. HYDE, MONTGOMERY AND ORMSBY, PFAHLER AND SCHMIDT.

DR. W. A. PUSEY, Chicago—It is constantly said that we are in the dark, both as to the indications for the use of *x*-rays and as to the means of applying the agent, and that the whole question is still experimental. I wish to emphasize that these papers all indicate just the reverse facts. The writers are from different parts of the country and have arrived at their results independently, and yet they all present practically the same findings. I know of no method of treatment used in any disease concerning which the observers are more unanimous in their reports. Men differ as to the minor details, but in the larger and more essential facts it is remarkable that the agreement should be so close. I am pleased to find that the experience of the different writers and their opinions correspond so closely with my own.

I have reported my experience in the use of *x*-rays in malignant disease very recently, and, therefore, I will not attempt here any discussion or any report on my own cases.

Regarding epithelioma Dr. Pfahler refers to one case that got well after treatment was stopped. I have a most interesting case of that sort in my records now. In my article in THE JOURNAL of the American Medical Association, April 12, 1902, I recorded among other cases one of orbital carcinoma which I had discharged as hopeless. It was a carcinoma which had destroyed the eye, involved the entire orbital cavity and spread within the cranium. After two months' treatment he was discharged as hopeless on account of the development of evidence of rapid intracranial growth. There was at the time of his discharge an acute dermatitis over the affected area. This was on Nov. 25, 1901. On April 30, five months later, I received a letter from Dr. T. Sprague of Sheffield, Ill., reporting that the disease has all practically disappeared, "the patient eats and sleeps well, uses no anodyne and has no pain." In spite of the fact that this patient was given up as hopeless he continued to get better for six months after treatment was dis-

continued. It seems to me that such a case puts us in a position where we can not refuse to treat carcinomas, no matter how apparently hopeless they seem to be.

One of the statements most surprising to me is the one sometimes made that patients show no idiosyncrasy to *x*-rays. There is no question that patients vary enormously in the susceptibility of their tissues to *x*-ray effects. Some patients will give a reaction in two weeks, while other patients under similar conditions will not show the same reaction in less than two months, and I believe it should be emphasized that we must pay close attention to this factor in handling our cases. I was interested to find that Dr. Montgomery has used this treatment in acne, psoriasis and blastomycosis. I have recently reported, in the *Journal of Cutaneous Diseases*, my experience in acne. I have seen no method of treatment in acne give results so surprisingly successful as those following the use of *x*-rays. I have also used the treatment with success in chronic inflammatory processes like psoriasis. I have recently treated a very extensive tumor of the knee, in which a diagnosis of blastomycetic dermatitis was made on the histologic findings, and the case has gotten entirely well.

Dr. H. W. Stelwagon, Philadelphia—There is one point not brought out in the discussion—the protection of the operator's hands—that I would be glad to hear about.

Dr. C. E. Skinner, New Haven, Conn.—As Dr. Pusey has just said, the experience of almost everyone is identical in this matter. I have had some 45 of these cases under observation during the past seven months; 6 of them have recovered, and the vast majority of the remainder are showing marked signs of improvement, some of them very marked. With regard to idiosyncrasy I have been much impressed by the prominence which it assumes in the problem. Some patients will exhibit evidences of dermatitis after two or three treatments, while others will accept an enormous amount of raying without manifesting any reaction, apparently. I use pure sheet tin for protecting the sound skin, and it has given me entire satisfaction. Thick rubber sheeting is recommended for this purpose by Dr. Albert C. Geyser of New York, and it is perfectly effective as a protective. In addition it has the advantage of not drawing off current from the terminals of the tube. For the protection of my hands I use an ordinary glove backed with rubber sheeting, one-eighth of an inch in thickness.

My results in the matter of scar tissue after healing have been extremely good. I have observed contraction and hardening of the skin in but one case. The original pathologic condition in this case was a large, deeply broken-down sarcoma of the neck. It healed very rapidly, requiring only six weeks, and in some spots the skin is considerably hardened and tight. Relief of pain is a phenomenon that has followed the application of *x*-radiance in nearly every case that I have treated. This has held true even in the deep abdominal cases.

A fact that I consider worth mentioning is that the brush discharges from the positive pole of the static machine given in alternation with *x*-light during successive seances, will sometimes hasten the progress of a case. This was first suggested to me by Dr. William Benham Snow of New York, and I used it first on a case of lupus that was proving refractory to *x*-radiance alone. Since then I have seen it act most kindly on cases of superficial cancer that had broken down, and which were not apparently making any advance, or but little advance, under *x*-light alone.

Another point that has excited my attention is that discontinuance of the application of the rays after the patient has had a few treatments does not always mean cessation of the curative process. For instance, I recall one case of epithelioma of the lip, the size of a half dollar, which I had treated for several weeks with but the slightest evidences of improvement. He was then attacked by the grippe, which laid him up for five weeks. He then appeared for resumption of his treatments, but his cancer had in the meantime diminished to the size of a silver three-cent piece.

As to whether or not there is a choice as between the static machine and the coil, I will state that I use both. In the superficial cases I do not think it matters which is used, but in the deeply-seated cases the static machine is, I think, to be preferred. In many superficial cases the cure will be hastened by getting up a little dermatitis, and here the coil through its unquestionably greater tendency in this direction, offers a questionable superiority. In deeply-seated cases, however, the end to be attained is penetration with as little integumental disturbance as possible, and here the static machine undeniably has the advantage.

With regard to what Dr. Schmidt said, that the anode of the tube should not be heated red hot for the purposes of x-ray therapy, I will state that my anodes are nearly always red hot and frequently white hot. It seems to have made no difference and the cases have gotten well just the same. In the case of the large sarcoma of which I have just spoken, I used a static machine and pushed the tube as hard as I could at each treatment, and the anode was always white hot, yet he got well with only seventeen treatments. This tube also, by the way, was of high vacuum, which I think disproves the idea that many of us used to hold, that coil currents and low vacuum tubes constituted the only apparatus capable of curing cancer. I do not think that heating anode exercises any influence on the curative properties of the rays, except in so far as that the radiance reflected from an anode excited to this degree ordinarily possesses greater penetration and greater volume than when the anode is backing up a current, the intensity of which is low enough to allow it to remain cool.

Dr. C. W. Allen, New York—I think this Section has the distinction, and I regard it a proud one, of being the first gathering of scientific men in this country to acknowledge and to put on record the fact that the *x*-ray treatment of some skin diseases and of certain cancerous diseases is no longer in the experimental or doubtful stage. I had watched the work of Dr. Pusey and watched it carefully, and I saw results from his work which I did not know how to obtain in any other way, and so I took up *x*-ray therapy to aid me in my work, and it has aided me materially, and I would be very loath to-day to give it up. I think with the aid of the rays we can obtain results that can be obtained in no other way. I am not in a position to say to-day that *x*-rays will cure cancer, but I can say that with their aid one can cure many cancers. You have got to have behind your *x*-rays a knowledge of the conditions present, a knowledge of your patient and a knowledge of medicine; you have got to study the case and use at times other measures, and always care and judgment. The doctor who knows what he is about can cure a great variety of cancer with the aid of the *x*-rays. But I think a note of warning should be sounded, and if I do nothing else to-day I want to say that I believe unless we move very carefully *x*-ray treatment will fall into disrepute and it will get a black eye. Patients will die now and then and there will come a public resentment against it because a next-door neighbor died quicker under the rays than he might have died without them. The *x*-ray is a powerful remedy to use, and you can kill with it as well as cure. You say you can not experiment, and you turn severe cases over to the man with the *x*-rays. It is possible that radiotherapy may hasten the death of those patients. They are suffering from a severe disease, and you are going to use something to get rid of the poisonous material that is in the system. That patient needs the most careful and conscientious physician, and that patient needs watching from moment to moment, and the treatment may save.

I am glad to hear Dr. Pusey speak of that patient who recovered after he had given him up. I can report a somewhat similar case. I treated a physician for cancer of the rectum who showed great improvement, but he had to stop treatment because of an intercurrent trouble. He had improved for two or three weeks, very markedly, but he had to stop. He was in such a condition they had to give him chloroform, and after a few days all the physicians who saw him said he was going to die. In twenty-four hours another consultation was held, and they said he would probably not last over forty-eight hours, and all attempts at medication and nourishment were stopped, as nothing could be retained. His condition was surely most grave. Suddenly, however, he began to improve, his severe symptoms gradually disappeared, and in time he began to

retain nourishment and then to sit up. He says he is going to resume the *x*-ray treatment, which he is sure has been of great benefit. I think the effect of the *x*-rays is still going on in his case, and that he is still benefiting from the treatment long after it was interrupted.

I have had some interesting cases. A boy of 15 has xeroderma pigmentosum and multiple epithelioma of the face. The eyes are involved and one has been destroyed. He is not cured yet of the lesions, but will be, I trust, after further treatment with the *x*-rays. The other eye is improving very much, and I hope it may be saved.

In another patient there was an ulcer on the side of the nose. He was treated in various ways by many physicians for two years, but the ulcer would not heal. I gave him twelve *x*-ray treatments and it healed up with a good firm cicatrix.

The *x*-rays are now being tried in all kinds of skin diseases, but probably after a year or two we will use them in a very limited number of cases only, perhaps in obstinate and persistent diseases like psoriasis, lupus, sycosis and some others.

I want to say a word about the idiosynerasy to the *x*-rays, for I believe we should all be concerned with the idiosynerasy of the various cases that come under our treatment. Individuals can not all be burned alike from the sun, and there is no reason why the *x*-ray should produce the same effect on all subjects. When Dr. Pusey was in New York he came to see me, and in showing him my technic I exhibited several patients, and I burned at least three patients the day he was there. Up to that time I do not think I had a burn, but I was letting my light shine, and perhaps let it shine too much. I asked him to criticise my work, and he answered in a very kindly spirit, "The only thing I can criticise is that you are using too great intensity of light." The results seen a week later proved the correctness of his judgment, of which I was conscious at the time. I believe you can burn almost any patient. I do not think it is only the occasional patient who has the idiosynerasy; you can burn almost anyone if you go about it, and conversely most burns are preventable.

DR. G. B. MASSEY, Philadelphia—In connection with the question of *x*-ray burns of the hands I may quote a suggestion that a pair of gloves might be painted with metal paint, such as silver or bronze paint. It was claimed that such gloves were opaque to the rays.

I am convinced there is great value in the *x*-ray treatment for some forms of superficial cancer, and yet it seems to me in these skin cancers we have means already at hand that will be much quicker and surer, in the shape of zinc and mercury cataphoresis. So far as I have seen, these superficial skin cancers could be completely destroyed by this method in thirty minutes, and possibly under the use of cocain without general anesthesia. In the use of this zinc-mercury cataphoresis small points of zinc are amalgamated with mercury and inserted into the growth for the formation of oxid of mercury and zinc, under electrolysis, the product being diffused by cataphoresis. This application by cataphoresis devitalizes the whole of the growth, and at the same time sterilizes the slough and a region surrounding it. I had such a case on a man's arm, recently brought to me, which had been diagnosed as epithelioma. It was about three inches long and little more than skin deep. The skin had been destroyed and the disease had involved some of the superficial layer of the muscles of the forearm. He was a workingman, and was brought in by his employer, who was very anxious not to lose his services. I told him it was a case in which the *x*-rays should be tried, but it would take some time to ascertain if they would be effective. There was also a slight possibility of burn. On the contrary, if he wished the cataphoric method tried he would have to go to bed, would have to be prepared for an operation, hire a nurse, and would have to lay off for some time, but the chances were certain that the growth could be destroyed in thirty minutes. The patient selecting cataphoresis, the arrangements were accordingly made, and the method applied at his home under general anesthesia, and a current of 350 milliamperes. I prepared a leash of fine wires, twenty-five in number, and attached to each a zinc needle, amalgamated with mercury at the tips. The wires were plaited in groups of six, so that the wire would not snarl during the operation, and when the current was turned on the points were thrust into the growth in close proximity. So rapid was the effect that when five or six points were inserted the first of the series had to be withdrawn, as we wished only a slight action. In thirty-five minutes the whole growth was destroyed, an area of about three and one-half by three inches. He had no pain the next day, the nurse was sent home, the man lost only a few days' time, and it is completely healed. This is an illustration of the fact that we may be going a little too fast with the *x*-rays. I have recently applied the method just described in a minor way in a case of tuberculous glands of the neck, and succeeded in healing six or seven large tuberculous sinuses of the neck that have been open for six or eight years. The other side of the neck had been thoroughly scarred up by repeated curettements. So promising was the result that I thought I had the patient nearly well, but six months later a general swelling began, showing that there were a large number of slightly-enlarged glands deep down in the neck. I then used the *x*-rays to the swollen part, and she is improving steadily without any particular dermatitis being apparent.

DR. W. T. CORLETT, Cleveland—I think we are all agreed that the *x*-ray treatment in some diseases of the skin, and especially in epithelioma, has passed the experimental stage, and is a very valuable therapeutic agent that is going to stay. Doubtless we all have our favorite methods of treating slight epithelioma. For a number of years I have used electrolysis, which I have found excellent and most efficient. It has many points in its favor, but all cases can not be treated in this way. There are a certain number of cases that are inoperable by the knife, by caustics, or by any method hitherto employed. In such cases the greatest value of the *x*-ray may be found. Recently I had a case under treatment of epithelioma of the face involving both eyes, in which I had endeavored by various methods to eradicate the disease; electrolysis had been used, caustics had been thought of, but on account of the eyes it had not been attempted, and even surgeons had held out little hope. We were then considering the use of the *x*-ray—at that time I did not know that the *x*-ray was harmless to the eyesight; in fact, I was devising a pair of metallic spectacles to protect the eyes, when the patient disappeared. Some months later the patient came back to the clinic practically well. He said he had been to Edinburgh for treatment, and when I took him downstairs and showed him what we were doing he was very much chagrined to think he had taken such a long journey. I repeat, in such cases we get possibly the greatest benefit from the *x*-rays. Aside from epithelioma, treated of so ably by the other speakers, I have used the *x*-ray in other diseases of the skin. In a well-marked case of eczema, I resorted to different methods of treatment without much avail, when finally she was subjected to eight exposures of the *x*-ray, with a complete disappearance of the eruption. My first experiences with the *x*-ray were followed by disappointment. I did not know the importance of the tube, and that much depends on the one selected for different uses. Nearly three years ago I exposed a case of lupus erythematosus to the *x*-ray without any benefit. Twenty exposures were made. I finally discovered that tubes used continually soon become hard, and that I had been using a hard tube. I believe many failures in the use of the *x*-ray occur from improper tubes and faulty technic. I regard, therefore, Dr. Schmidt's experience as to technic as an extremely valuable contribution.

DR. R. R. CAMPBELL, Chicago—That idiosyncrasies do exist in this as well as in other lines and methods of treatment was pretty conclusively demonstrated to my mind in a case of tuberculosis verrucosa cutis which I had had under treatment for some time without any apparent improvement. I finally concluded to burn him. I took a tube of low vacuum and placed it at a distance varying from one to five inches from the seat of the eruption. After two weeks of daily exposures of 15 minutes each, I succeeded in burning the patient; the patient then disappeared for two weeks, and on his return, rather to my astonishment, the disease was almost well, and the dermatitis had almost subsided. I worked for 10 days to burn him again, then allowed the patient to stop all treatment

for a month, at the end of which time all evidence of the disease had entirely disappeared. This experience is quite in contrast to that of Kienboeck, who claims that idiosyncrasy does not exist. While we would hardly expect a recurrence in psoriasis to appear within a couple of months, I was glad to hear Dr. Montgomery's results in treating the disease with the *x*-rays. My experience in treating acne and rosacea with the *x*-rays quite corresponds with Dr. Pusey's, and I have obtained most satisfactory results in the treatment of intractable cases of both of these conditions. Varney, in discussing the treatment of lupus by the *x*-rays, compared the stimulating influence on the tissues with the similar action and results of Finsen's phototherapy. He stated the results are about the same, except that the *x*-rays are somewhat more rapid in their action with shorter exposures, and larger areas may be treated at a sitting. The treatment by *x*-rays is painless; its exposures are of shorter duration and the areas treated may be of almost any size and location. In the treatment of malignant conditions by the *x*-rays, considerable area beyond the actual lesion must be exposed, while in the treatment of lupus and like diseases only the active condition or surface is to be exposed.

Puncturing of a tube is, as a rule, the result of increasing the sparking pressure of the electrical current beyond the internal capacity of the tube. Certain applications of the foil to reduce a high resistance increase the risk of puncture to the tube, as the foil approaches the cathode or anode and in proportion to the sparking pressure of the bombardment.

Dr. Beverley O. Kinnear, Clifton Springs, N. Y.—I have believed for a number of years that the central nervous system has much to do with the origin of skin diseases. I have treated a number of cases of eczema and herpes zoster, successfully and speedily, by the application of cold over the spine in the Chapman spinal ice bag. From this experience it seems to me that there must be an excitement in such disorders of the vasodilator nerve centers, which anatomically terminate in all tissue cells, and this may lead at first to redness and arteriole dilatation of the cutaneous blood vessels, with thickening and exudation, accompanied by itching and burning; or if it goes further to elevation of the cuticle and fluid exudations, as in eczema, and herpes zoster, according to the force of the nerve current. Then the query naturally arises, whether the nerve central excitement is not the direct cause at least of the skin disorder, though there may be underlying causes which induce the hyperemia, or excitement, or increased function, of the nerve centers supplying the skin. I ask also whether in the use of the *x*-ray any effect has been noted on the arterial circulation. Cold over the spine in spinal ice bags of the proper width will induce activity of the circulation all over the body, giving rise thereby to rapid molecular change, and I have healed large ulcers and absorbed exudations by this method of treatment. I would like to ask if any expert in the use of *x*-ray treatment has observed increased activity of the arterial circulation under the use of the *x*-ray. If this be so, I think it one way in which we may account for the results obtained by the *x*-ray in cases of epithelioma.

Once more, let us take the burn produced by the lighted end of a cigar—a most painful burn. The most efficient and speedy way to relieve the suffering caused by such a burn is to hold the injured part over a lamp or a hot fire. The suffering will be much increased for a few moments, but the cure is radical, and the pain ceases. May it not be possible, then, that the burn induced at times by the *x*-ray will act beneficially on an epithelioma, inducing a sedative action on the excited nerve centers; which excitement may be the direct cause inducing the epithelioma?

Dr. H. R. Varney, Detroit—In answer to the question of the last speaker regarding the effect on the circulation, in applying the rays to the tail of the tadpole, there seemed to take place a change which was, I think, almost identical with a normal inflammation. I watched it before and during long exposures. The first change apparent was a slight increase in the blood current, followed very shortly by a slowing of the same. There was an increase in the number of blood cells, the white increasing more rapidly than the red. The white corpuscles passed through the lumen of the walls and surrounding tissue until the whole area was a field of cells. In producing the physiologic effect of the rays, what I deem an erythema, or a dermatitis, is produced, and I believe this condition to be a normal process of repair, an ordinary inflammation of tissue. My experience with the rays in the treatment of epithelioma and other skin affections, has been to produce a physiologic effect. I find it can be done more safely with a static apparatus than with the coil. I give daily exposures until this effect is produced, when the patient is discharged for ten days or two weeks, after which, if it be a case of superficial epithelioma or ulcer, he returns practically, if not entirely, healed.

Just here, I would like to ask the men who are working along this line, whether they have noticed any severe cases of rheumatism reflected after exposures to the ray. I have several such cases after treatment has been given from a week to a month, and for the first time in the history of the patient. I would like to know whether any increase of solids has been noticed in giving this treatment, and if a toxemia is not produced, that will account for this painful condition resembling rheumatism.

Dr. M. L. Hiedingsfeld, Cincinnati—My experience at the present time dates a little over a year, and for the treatment of certain conditions, lupus vulgaris, dermatitis hiemalis,[1] and for certain forms of epithelioma, I am very favorably impressed with its use. I am also very favorably impressed with the relief which *x*-rays afford to the distressing symptoms, which occasionally accompany keloid, and recall one case, keloid of the left arm in a physician's wife following a burn from cleaning a full-dress glove with gasoline, where the relief has been almost a godsend. In some other conditions I am not so favorably impressed, particularly the treatment of alopecia areata after the method of Kienboeck. The obdurate character of several of these cases[2] which successfully resisted for more than a year all ordinary therapeutic measures recommended: chrysarobin, oil of mace, glacial acetic acid, pyrogallis acid, cantharides, etc., induced me to try the *x*-rays. A favorable case of alopecia areata circumscripta with multiple patches afforded me an opportunity to determine its efficacy by means of a control experiment. The *x*-ray was limited to one patch, another was left untreated and the remaining were subjected to the action of trikresol as recommended by McGowan of California. After an interval of about twelve weeks the patches treated with trikresol were richly covered with a luxuriant growth of lanigo hair and the untreated area and the area exposed to the *x*-rays remained unchanged. Trikresol was then applied to the remaining patches, with the result that the untreated area promptly recovered its hair, and the *x*-ray area has made but little improvement after a subsequent interval of almost two months. The *x*-ray has, therefore, retarded rather than aided the progress of this case.

Another affection, in which I believe the *x*-ray is not always productive of the best results, is lupus erythematosus. My experience may have been singularly peculiar in this affection, but every case which has been subjected to *x*-ray influence, however brief, has been followed by a rather intense and distressing reaction.

Dr. David Lieberthal, Chicago—About a year ago I was still skeptical about the value of the *x*-ray in the treatment of cutaneous cancer after having subjected it to a case of epithelioma, developed on the scars of lupus vulgaris, for a period of three months without beneficial results. Shortly afterward the epitheliomatous matter was removed by Dr. L. Greensfelder at the Michael Reese Hospital, the defect being covered by a flap, the results of which operation he will report in the near future. But since I saw the excellent results which Dr. Pusey exhibited I lost a good deal of my skepticism and I am employing the *x*-ray now in epithelioma as in various affections of the skin.

Although we can not expect to obtain good results in every case, we have nevertheless a valuable method in the *x*-ray. As in deep-seated or extensive carcinoma it is well first to ascer-

1. See discussion on Dr. Corlett's paper on dermatitis hiemalis, The Journal A. M. A., Dec. 20, 1902.
2. Cincinnati Lancet-Clinic, September, 1902.

tain the opinion of the surgeon, so it would be advisable to consult the dermatologist before the *x*-ray is applied for an affection of the skin.

Regarding my own experience with it, I can report the following: Two cases of epithelioma originating from senile warts, both cured; five cases of ringworm of the scalp in which from six to twelve exposures produced total alopecia in the areas treated and in which the slight irritation soon subsided, and subsequent repeated attempts at cultures from the hair follicles proved negative; and one case of cutaneous tuberculosis which yielded splendidly and is healed over. Cases of acne rosacea and psoriasis showed improvement.

DR. PUSEY—I have not seen rheumatism that could be apparently attributed to the treatment with *x*-rays. Several gentlemen have spoken in this discussion about some poison being liberated in the system from neoplasms degenerating under *x*-ray treatment. I believe that there are no good grounds for such assumptions. It is theoretically possible that such a liberation of poisonous material might occur, but I have seen nothing to indicate that it does. I have seen large masses of carcinoma tissue and of gland tissue in Hodgkin's disappear, and I have never seen any symptoms to indicate that there was a liberation of any substance in the destruction of these tumors that in any way affected the patient's condition.

DR. C. E. SKINNER, New Haven, Conn.—In deeply-seated abdominal cases my experience so far has been that we do secure improvement usually and that we ought not to consider the rays inefficient in this situation as yet. It is only a question of how far the improvement can be carried. Up to the present time the improvement which I have noted has consisted of increase in weight, relief of pain, increase of appetite, and lessening of discharge where any was present. In one case of cancer of the uterus involving the bladder and rectum, improvement along these lines was marked and in addition the growth itself had diminished in size as a whole. All of a sudden, however, she developed uremic symptoms and died in a week. In view of the fact that she had been improving markedly up to this time, the sudden development of renal trouble might be construed as indicating that a toxin of some sort had been developed or liberated. I think we ought to be careful to recognize and weigh all the elements that appear in these cases.

DR. MONTGOMERY—Dr. Allen has very properly called attention to the danger of radiotherapeutics in the hands of the unskilled and inexperienced. We shall be fortunate, indeed, if, for a time at least, more harm than good is not done with this comparatively new therapeutic agent as the result of its indiscriminate use by those who lack the requisite skill for its successful and safe administration. Papers like the excellent one just read by Dr. Schmidt, giving full details of technic, will be of great value to those desiring to take up this work; but even with full instructions the beginner can not be too cautious in acquiring the experience necessary to a safe use of this somewhat uncertain therapeutic agent. There is a tendency to use the rays for all sorts of cutaneous and other disorders for which we have no other specific treatment, and there is no doubt that we are all using them now in a tentative and experimental way in cases for which the older and better understood methods will prove to be preferable. In other words, it is probable that as our experience enlarges we shall find that radiotherapy and phototherapy, while exceedingly valuable in certain disorders, will have a narrower field of usefulness than that in which we are now trying to apply to them. We have had good results in a few cases of acne and rosacea. Dr. Pusey refers to the use of the rays in a case of blastomycosis. In two of our recent cases, areas which persisted after a long course of potassium iodid disappeared quite promptly after a few exposures to the *x*-ray.

The matter of personal idiosyncrasy is, I believe, an exceedingly important one, and I am glad that the other men have spoken so strongly on this subject. Practically the only guide we now have in the treatment is the reaction in each individual case.

It has been suggested by two speakers that the Finsen light was for all practical purposes identical with the *x*-rays. The immediate results of the treatment are quite different. With the Finsen light an exposure of ten or fifteen minutes will result in a dermatitis often vesicular or even bullous. Reaction occurs within twelve hours and disappears in a few days. No deep burn is ever produced. On normal skin pigmentation follows such a reaction and serves to protect the tissue from the light, so that a second treatment produces, as a rule, little or no reaction. In the diseased areas this protective pigmentation does not take place, and the reactions to successive exposures are like the first. With the *x*-rays, on the other hand, not only is the reaction slower in appearing, more persistent, and deeper seated, but reactions to successive treatments on both normal and diseased areas come, as a rule, more promptly and are more severe than those obtained from the first application. As to ultimate differences, we have found cases of lupus erythematosus and at least one case of lupus vulgaris in which the Finsen light has proven more effective than the *x*-rays. In at least one case of verrucous tuberculosis and in some other cutaneous affections the *x*-rays have given excellent results where none was obtained with the Finsen light. Our experience is as yet too limited to let us determine accurately the factors which cause one method to be more effective than the other in a given case.

DR. PFAHLER—I want to correct the statement of Dr. Pusey that I said no case of cancer had been cured. My paper states that cases have been cured and others are still improving under treatment. Another point that was brought out in the discussion was the protection of the hands of the *x*-ray worker. I use a mitten made of chamois skin covered on the back with lead foil and a piece of adhesive plaster over the foil. In regard to the point of heating the platinum anode, I always have my anode red hot, often white hot. I fully agree with Dr. Corlett and Dr. Allen that this is not only a very valuable therapeutic agent, but also a dangerous one.

DR. SCHMIDT—I think a large number take no precaution whatever to protect the hands of the operator. In fact, I think there is nothing to be applied or that can be applied to prevent the *x*-rays doing any damage, if an idiosyncrasy of the individual exists. The patients that come to us with *x*-ray dermatitis are those who do a great deal of photographic work. They handle chemicals and then possibly with the action of the *x*-rays a dermatitis is readily set up.

In regard to what Dr. Skinner said about heating the anode red hot or white hot, I am pretty positive that when we take a large number of workers in this field they will agree, if such a condition occurs, the tube is of a very low vacuum, and in addition to that, there is an excessive amount of electricity passing through and some of the electric energy is converted into heat rays instead of *x*-rays. If any such condition exists for a long time, a puncture of the anode may readily occur.

TREATMENT OF FRACTURE OF THE NECK OF THE FEMUR.*

CHAS. E. THOMSON, M.D.
SCRANTON, PA.

For fifty years or more we find a sentiment pervading medical literature on the subject of fracture of the neck of the femur; that it is an irreparable injury; that a large percentage of these cases, being old, die of the trauma and shock following the accident, or the complications incident to it, viz.: Hypostatic congestion of the lungs from recumbent position or sepsis from bed sores; that the majority of those cases who live remain permanently disabled, getting about only on crutches or canes, on a badly deformed or functionally weak limb, the so-called "fibrous union." In support of this sentiment allow me to quote from the days of Sir Astley Cooper down to the latest literature obtainable, as taught in text-books on surgery, medical journal articles and medical schools.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.

THE OLD TREATMENT.

Cooper.—In reference to the first-named author, that great surgeon admits that he had never seen bony union in a case of intercapsular fracture of the neck of the femur. His treatment consisted in placing the limb on a long pillow for ten days or two weeks, afterward allowing the patient to be up and about on crutches.

Samuel D. Gross, in his admirable work, Vol. I, p. 1027, commenting on the treatment of Sir Astley Cooper twenty years ago, considered it too pessimistic and added that for many years he had been in the habit of treating fractures of the femoral neck (intercapsular) as any other fracture of the femur, viz., extension and counter extension, not with the hope of obtaining bony consolidation, but with the view of keeping the ends of the fragments in more accurate contact and thus affording them an opportunity of becoming united by fibro-ligamentous tissue.

Agnew.—Writing one year later, Vol. I, p. 931, the great Agnew also criticised Cooper's treatment and advised treating fracture of the femoral neck on the same general principle as fractures elsewhere in the bone, viz., by extension on a straight or an inclined plane, adding that we have seen enough of fractures that were "believed" to be intercapsular recover with bony union to justify such procedure.

Eckhart Mines, Md., *North Carolina Medical Journal*, January, 1885, Vol. xv, p. 309. Youth of 18, crushed by fall of coal. Two inches shortening, inversion, no crepitus. Diagnosis: "The readiness with which the leg is brought down, absence of crepitus, coupled with the fact that after five weeks no attempt at union, nor discoverable callus thrown out, warrants me in believing that the fracture is within the capsule. Treatment: leg supported by pillows three weeks, Porter's modification of Smith's ant. splint, two weeks, further treatment useless. Allowed on crutches. Condition at writing: Shortening apparent enough, wears a high heel and walks with a peculiar rolling gait."

Dr. Swing, Coatesville, Pa.—Lost 16 cases out of 18. All died in from six to nine weeks. Ages 70 to 80. Treatment: extension, counter extension and weights to limb and sand bags. Cases developed bed sores.

In subsequent case allowed patient to move about on mattress, got well with shortened everted limb, but could walk about her room last year of her life. Two years later second case could walk with crutches after two months, limb shortened and everted, lived one year. The doctor considered "the only rational" treatment to be to allow patient to move about on mattress of hair. He finds they will get well if spared the necessity of useless apparatus and will recover with as good a limb as they are likely to have if they could survive the torture of the apparatus. This treatment saves life and suffering. All treatment should have these two ends in view, rather than the glorification of the surgeon in displaying his skill in adjusting apparatus and setting limb. He feels sure that some of his cases would have gotten well if they had been "let alone" instead of receiving the orthodox treatment. He concludes by saying "the surgeon is not a mechanic to adjust appliances, but one whose judgment and experience should determine their necessity."

Everhart, Scranton, Pa.—I am indebted to Dr. Everhart for report of the following case: Mrs. H., aged 71, in 1896 fell down stairs, was picked up and put to bed, about ¾-inch shortening, suffered considerable pain, but did not have much deformity for four days, when she suddenly sneezed and at the same time felt something give way in the hip. Upon measuring the hip 1½ inches shortening was found. The limb was markedly everted.

June 7, 1902: patient is still in bed, where she has remained for six years; 2 inches shortening, marked external rotation. Patient suffers great pain in hip, which is aggravated on slightest movement.

Corser, Scranton, Pa.—I am indebted to Dr. John Corser for report of the following case: Mrs. C., aged 65, in 1887 fell, fracturing her hip; patient was put to bed, where she remained for 15 years, when she died of exhaustion. During all these years was unable to walk or help herself in any way.

W. Pugin, Thornton, April 2, 1894.—Patient, aged 87, was knocked down by horse, chloroformed, crepitus found, long splint, four nurses for 3 weeks. Water bed for one month. Got bedsore while on water bed. May 2 splint taken off and sand bags used. Four and a half months in bed, now goes about in bath chair; is able to walk a short distance with crutches. I do not expect he will improve much in this respect on account of his age.

Oscar H. Allis.—*Medical Times*, August, 1883: "From first to last I make the patient my first care and regard the fracture as of secondary importance." He recommends getting patient up in rocking chair at end of first week, and from the first daily shiftings in bed. He thinks that getting patient up daily, carefully, does not produce separation of fragments. "In conclusion, I ask what has been, is and must ever be the outcome of all this? Will the surgeon risk his little all for the good of his patient or must he steer his course for that true but selfish standing, 'Self preservation is the first law of nature.'?"

Henry Lehenan.—Read March 19, 1894, before the Philadelphia County Medical Society: Mrs. ———, aged 60, fell Jan. 23, 1881, while attending household duties; was not dizzy at the time. Saw her first Jan. 24, 1881. She was then lying on a couch and was unable to stand or move about. On examination, from the preternatural mobility, intracapsular fracture was diagnosed. My attendance was continued at intervals during the months of February, March, April and May. She was not able to help herself in any way. By help she could be gotten on a Charleston chair, and this was the only treatment attempted. The most of her pain was in the adductors; there was shortening and eversion of toe. She continued in the same room and on the same couch and chair until I was called to see her, Jan. 6, 1884, when I found her dying from exhaustion. She died January 8. Permission was granted to examine the hip. Specimen here presented was obtained. The acetabular cavity was normal in appearance. The head of femur lay in cavity free. The socket and head of bone were covered over with a membrane firm but somewhat incomplete. Upon this surface the upper extremity of the femur had formed an artificial joint, the neck having been absorbed. In the surrounding tissue on the inner side was a fragment of bone 1½ inches long.

Scudder.—"In case of fracture of the neck of the thigh bone occurring in elderly individuals, treat the patient and let the fracture be of almost secondary importance." Again: "The impacted cases will unite; the unimpacted may unite." And again: "In only two cases out of sixteen could it be said that the leg was functionally useful."

Park.—"Treatment must be so ordered as to save life even at the expense of an imperfect leg."

Berger.—Gould's Year Book, 1897, p. 357: "In articular fractures those only in which operation is justifiable are about the elbow and knee, because an imperfect result here means a most grave functional loss."

American Text-Book of Surgery.—Page 310, 1892, recommends extension and fixation with sand bags and plaster of paris, and in ununited fracture reports that several cases have been cut down on but fail to give results of such operations.

Curtis.—"In certain cases, of over 60 years of age, give up the idea of bony union."—From lectures on surgery, University of New York.

From the above it is apparent that at least a goodly number of our authors have been rather skeptical about obtaining bony union in those cases, and in discussing the subject, both in medical societies and in private conversations, I find the average practitioner—under whose care those cases are usually treated—is satisfied if his patients are able to hobble about on crutches for the remainder of their lives, nor has this pessimistic standing been confined to cases treated by ordinary methods and general practitioners.

THE OBTAINING OF BONY UNION.

BRYANT.—Having reported 6 cases from König, Cheyne, Myre, Gillette and Curtis, all of whom obtained firm bony union and strong useful limbs, Dr. J. D. Bryant, in his valuable work on operative surgery, vol. ii, p. 1279, 1901, concludes as follows:

"There is yet a reasonable doubt regarding the advisability of this operation except in special cases. The difficulty of securing and maintaining proper adjustment of the fragments because of the lack of command of the inner portion, its porous character and low vitality, present obstacles to success that can not be gainsaid. The degree of shortening that follows the successful results suggests an initial failure of reduction of the deformity or the maintenance in proper place, and bespeaks in any event a considerable amount of absorption at the seat of the fracture. A more extended experience is needed and a careful comparison of the favorable results by different methods of treatment is required before a final judgment can be recorded."

BERGER.—Gould's Year Book on Surgery, 1897, p. 357: "In articular fractures those only in which operation is justifiable are about the elbow and knee, because an imperfect result here means a most grave functional loss."

Is not the hip joint an important one and quite as worthy as the elbow and knee of our special consideration? I am pleased to add Cases 5 and 6 to the successful operative list, and hope that others may be added in sufficient numbers to put the operation out of the experimental class beyond all doubt, even in the minds of the most skeptical.

Among the authors that have written more hopefully on this subject are Hamilton, Wyeth, Dennis and Ridlon.

RIDLON.—The last-named surgeon, in his excellent article on treatment of fracture of the femoral neck, Annals of Surgery, July, 1901, has so fully expressed my views that I take the liberty of quoting from it as follows:

"Let me assure you, gentlemen, that in all these cases a strong and useful limb, in good position, may be as confidently anticipated as in any other fracture of this bone or any other bone. In no other fracture is the surgeon's task easier; in none is a good result more certain." Again: "I believe we can only treat the patient properly, by properly treating the fracture from which she is suffering and likely to die." And again: "The average surgeon treats fracture of the neck of the femur precisely as he treats a solution of bony continuity where he aims to get a false joint; and, verily, he usually has his reward. My plea is simply this: Show the fracture at the neck of the femur the same consideration that you show all other fractures. It is useless to quibble about fractures within the capsule and fractures outside the capsule; fractures impacted and fractures unimpacted; about the thin, weak bone of fat old women; these cases invariably result in strong and useful union if they are given a fair chance."

I cannot possibly improve on the above quotations, nor write anything that more aptly expresses my views. I could never understand how any thinking man can pretend to benefit his patient in any way by leaving a fracture unreduced and unimmobilized. I suppose men who have never reduced nor immobilized a fractured femoral neck cannot be expected to have noticed the great relief given to a patient by such a procedure.

METHOD OF TREATMENT.

I regret that I have to differ from my friend, Dr. Ridlon, in his method of treatment, yet I believe he has the most complete and efficient apparatus ever devised for the treatment of fracture of the femoral neck, but such apparatus is made well only by skilled mechanics, whose work is expensive and hard to obtain when most needed. Then, again, each case requiring a specially made apparatus, a number of circumstances may arise causing long delay and loss of valuable time, while the patient is suffering from unreduced fracture and the friends are impatient because the limb has not been "set." All this care may be obviated by the surgeon who carries in his satchel sufficient material, and in his brain sufficient intelligence, tact and skill to make a plaster-of-paris spica. That a surgeon should stop before he really commences to treat a difficult case and wait for the whims and efforts of a mechanic is surely a reflection and a humiliation on modern surgery and should not prevail. Then, again, I think my friend has rather overestimated the task of putting up a fractured femoral neck in plaster-of-paris spica. Beside the man who is giving the anesthetic, all that is required is a McBurney hip rest and one assistant with sense enough to do what he is told, and strength enough to make the necessary extension. Then, again, they speak of disturbing the fracture by changing the plaster. I have never found it necessary to change a plaster cast on one of these cases, and have frequently left them on three months, or long after the patient was up and going about. It is not necessary to get these casts soiled, and as to excoriations and bed sores, they simply never occur, if the plaster is properly applied. On the contrary, I frequently put on a plaster-of-paris spica to cure a bed sore; by so doing you can distribute the pressure and support the circulation, two very important factors in the treatment of bed sores.

What cases should be operated on? No recent case. Why operate when we get such excellent results without operation? The two cases I have operated upon, of three and eighteen months' standing, respectively, were not even diagnosed before I saw them. I think a fair rule would be that any case that remained ununited for three months and had received judicious care, would be a case for operation.

Dr. Bryant has said, Operative Surgery, vol. ii, page 1287: "In operating on cases of ununited fracture the refreshing of the ends of the fragments is a necessary step in the technic." I made no attempt to freshen the ends of bones in my cases and yet I got prompt and firm union.

The method of treatment I have used and intend to recommend, simply carries out the principle of treatment of fracture in any other bone in the body, viz.: Reduction of fracture and retention of fragments in corrected position, for sufficient length of time to allow Nature to make the necessary bony repair. This I believe to be best obtained by anesthetizing the patient, so as to relax the muscles and enable the surgeon to ascertain the exact nature of the injury and more completely replace the parts. Impacted fractures should be very carefully handled. In fracture of the femoral neck this is best accomplished by having an assistant make forcible extension on the limb (while a second assistant, the anesthetizer, makes counter extension from shoulders) until it is drawn down to equal length with its fellow, while the operator manipulates the upper end of the bone, reducing the fracture as well as possible; and holds it while the assistant carries the limb into abduction of about 10 degrees. This position of abduction has a tendency to hold the fractured ends together, and facilitates in keeping the patient clean afterwards. The operator now applies shaker flannel bandages to the entire limb and body, as high as the arm pits, amounting to about four layers. Over this is applied plaster-of-paris dressing (reinforced with soft steel plates at hip and knee) sufficiently strong to maintain the form. During the application of the spica the limb is constantly held by the assistant in extension and ab-

duction as noted above. Care must be taken for the first twenty-four hours that undue pressure or strain is not brought to bear on the plaster before it is sufficiently dry to resist. If at any time the patient complains of pain over prominent parts, as the knee or malleoli, a portion of the plaster may be removed to relieve the pressure. After the plaster has become sufficiently dry the patient may be turned from side to side to relieve the hypostatic congestion of lungs, or for the purpose of bathing. If the spica is continued sufficiently high on the thorax it will not materially interfere with respiration. It is only when it ends at the free border of the ribs that patient complains in this respect. By this method of treatment the patient is enabled to materially assist in the use of the bed pan without the danger of disturbing the fragments.

SUCCESSFUL CASES.

The following is a list of my own cases, together with a number of successful cases from other authors, that I take the liberty to present.

SHEEHAN.—*British Medical Journal*, 1895: January, 1893, J. H., aged 91, knocked down by cab; two inches shortening, no crepitus. Treatment: Extension, weight and pulley, sand bags. Allowed up in a few days, on crutches, got about until his death from nephritis, April, 1894. Specimen showed bony repair in good position. Amount of shortening not given.

JOYCE.—Page 907: Dec. 28, 1895, patient fell while intoxicated, three-quarter inch shortening. Treatment: weight and pulley. Jan. 7, 1896, showed signs of pneumonia, propped up in bed, turned over; improvement followed. January 20, extension had to be removed as the skin about ankle and foot gave way. Next five weeks no treatment, but kept in bed. In three weeks walked with crutches. May 12, walked with two sticks, one inch shortening, complete bony union. Was since able to follow his trade of peddling.

ALEXANDER HATTEN, Portsmouth, Pa.—*New York Medical Journal*, Nov. 13, 1897: On Sunday, March 8, 1896, was called to see Mrs. C., aged 73; much emaciated, being about 5 feet 3 inches in height and only weighing 95 pounds. She had fallen while entering a church door and complained of severe pain at the left hip joint and lost motion in the left thigh. She was placed on a stretcher and carried to her residence, where on examination I found an intracapsular fracture of the neck and left femur with no impaction. She was placed on her back in a fracture bed and her leg put in good position. Buck's extension was applied and two sand bags were used, one on inner and one on outer side of leg, the latter extending up to waist. She remained in this position for six weeks, at the end of which time Buck's extension was removed, as it was found the fracture had entirely united. In three weeks more she was able to walk with the assistance of crutches. She now walks well without assistance and only has about one-half inch shortening.

AUTHOR'S CASE 1.—Mrs. C., aged 62, on August 19, 1901, was thrown from her carriage, striking violently on her hip. Seen by the writer three days later, limb everted, 2½ inches shortening, very painful. Patient chloroformed, fracture reduced, plaster-of-paris cast applied. Two weeks later was transported six miles over country road and 125 miles on railroad train to her home. Plaster left on eight weeks, when she was allowed on crutches.

Present Condition.—June, 1902, nine months after accident, limb in good position. Can walk without crutches or cane but uses cane on street. At present time is visiting friends and enjoying herself.

AUTHOR'S CASE 2.—Mrs. S., aged 66, 1897, sustained fracture of hip, 2 inches shortening, chloroform administered, fracture reduced and limb encased in plaster-of-paris spica, in extension and abduction. Cast left on for 8 weeks, when she was allowed on crutches.

Present Condition.—Has done all her house work for three years; walks with slight limp. Patient absolutely refuses to have limb measured.

AUTHOR'S CASE 3.—Mrs. F., aged 76, on Oct. 18, 1900, fell off porch 2 feet, striking on hip; 2 inches shortening, limb everted, great pain. Under complete chloroform anesthesia, limb placed in best possible position, plaster-of-paris cast applied and left on for nine weeks, during which time patient was kept in bed, and then allowed up on crutches.

Present Condition.—Shortening 1¼ inches, limb straight, 45 degrees free and painless motion. Walks without cane or crutch, no pain in hip, goes up and down stairs unaided although 78 years old.

AUTHOR'S CASE 4.—Mrs. P., aged 59, in April, 1901, fell down steps 4 or 5 feet, striking on hip; seen by writer one week later: patient in bed suffering a great deal of pain which was intensified on slightest attempt at motion; 1 inch shortening. Temporary plaster-of-paris spica applied. Patient transferred 4 miles over country road, and 20 miles on railroad train to hospital. Next day, under complete anesthesia, plaster-of-paris spica was removed, limb carefully examined and previous diagnosis of impacted fracture confirmed. Permanent plaster-of-paris carefully applied, patient put to bed for nine weeks, spica removed, allowed to walk on crutches.

Present Condition.—June 3, 1902, union firm, position and motion of limb normal, 1 inch shortening; can bear entire weight of body on limb without pain, and walks well without cane or crutch. Has done all her housework for 3 months.

SUMMARY OF AUTHORITIES ON OPERATIVE TREATMENT.

KOENIG.—The operative treatment in these cases was first suggested by Langenback, and successfully carried out by Koenig. The latter operated in a case of recent fracture, making a small incision over the trochanter major, drilled a hole through it with a metal drill in the direction of the head of the bone, applied extension to the limb to the extent necessary to overcome the deformity, and then drove a long steel nail through the canal in the trochanter into the head of the bone and left it there. The limb was then immobilized and extended for six weeks. There is no record of the ultimate shortening, but good union and free motion of the joint was obtained.

CHEYNE.—In a case of recent fracture, Cheyne exposed the fragments through a longitudinal incision made over the anterior aspect of the joint, exposed the fracture, made extension and internal rotation of the limb, and with the fingers in the wound manipulated the fragments into place; then a small longitudinal incision was made over the outer side of the trochanter major, and two canals drilled through the fragments at a distance of half an inch apart. Ivory pegs were then driven through the holes made by the drill, and the limb immobilized. Good union and motion were obtained, but there is no record of measurements of the limb.

MEYER.—In a case of ununited fracture with three inches shortening, Meyer made the Langenback incision for excision of the hip joint (Bryant's Operative Surgery, Fig. 393), exposed the seat of fracture, scraped the ends of the fragments until they bled, reduced the deformity by extension of the limb and fastened them together by driving two nails through the trochanter major. A useful joint was obtained, with an inch and a half shortening of the limb.

PARKHILL.—This method is commended for fracture of the neck of the femur (Fig. 1550 in Bryant's Operative Surgery).

GILLETTE.—Three cases of ununited fracture of the neck of the femur are reported operated on in the following manner: A horseshoe incision with its convexity downward was made, beginning an inch below and an inch posterior to the anterior superior spine of the ilium, carrying it down two inches below the trochanter major and bringing it up the buttocks to about the center of the gluteus maximus muscle. The skin and the two layers of fascia were dissected up en masse. A chain saw was then passed between the posterior border of the tensor vaginæ femoris and the gluteus medius, hugging the neck of the femur and the base of the trochanter major; it was brought out through the posterior surface of the gluteus medius and the anterior surface of the gluteus maximus; the trochanter major and its muscular attachments were sawed off, turned back, thus exposing the capsule of the joint. Then, by making a longitudinal incision into the capsule the fracture

could be easily seen. The surfaces of the fractured ends were denuded and a bone peg driven through the neck of the femur, thus holding the fractured ends together. The capsule was

Fig. 1.—Showing fracture before operation and atheromatous femoral vessels.

stitched with catgut, the trochanter major restored and nailed in place with a small bone peg, the skin closed and the limb immobilized. There was union and good motion obtained in

Fig. 2.—Showing hip after operation.

all cases, with shortening of from an inch to an inch and a half.

CURTIS.—In a case of ununited fracture of neck of the femur of three months' standing, Curtis exposed the fracture through an anterior incision, passed a drill into the callus and between the fragments to cause irritation, applied extension to the limb and reduced the deformity, after which a drill was passed through the trochanter major from the outer side, transfixing the fragments; the handle of the drill was then removed and the drill itself left in situ. The anterior wound was closed and the limb immobilized. The extension was maintained for six weeks, at the end of which time the drill could be easily removed. Good union and a useful limb were obtained with three-quarters of an inch shortening.

LISTER.—*British Medical Journal*, Aug. 26, 1871: Sir J. Lister has recorded the case of an ununited extracapsular fracture of the femur in a man aged 45, where, eighteen months after the injury, he cut down on the fragments with antiseptic precautions and gouged them, the fracture being then finally put up. Recovery was complete, the man walking well.

AUTHOR'S CASE 5.—M. M., aged 60, miner by occupation, on Feb. 7, 1900, fell on ice, striking on hip, was carried home and put to bed for three days, afterwards allowed to sit in chair, where he spent 3 months; could not put weight on limb for 18 months, had constant pain in hip, walked with both hands on cane (bent almost double) on which he carried the greater part of his weight, dragging his right limb; one and one-half

Figure 3.

inches shortening, marked eversion of limb, on manipulation distinct movement could be made out between head and trochanter (Fig. 1). On examination patient appeared much beyond 60 years, and showed signs of senile degeneration, viz., general muscular atrophy, arcus senilis, and atheromatous arteries (Fig. 2).

On Aug. 28, 1901, under complete chloroform anesthesia, a horseshoe-shaped incision was made around the great trochanter down through the muscles to the periosteum. In this case no bone flap was made, the capsular ligament was opened, and the free motility of the head ascertained. We deemed this step necessary because the skiagraph showed what we feared was ankylosis of head in the ascetabulum. I then drove two solid silver nails, 3/16 inch in diameter, and 2 and 3 inches long, respectively, through the great trochanter, neck and into head of bone. Only the long nail reached the head, as was afterward shown by *x*-ray (Fig. 2). It was not necessary to use drill before driving nails, capsular ligament was closed with catgut sutures, external wounds with silkworm gut without drainage, aseptic dressing applied and entire limb and body encased in plaster-of-paris spica. Patient did not suffer from operation, was allowed to turn over in bed, no elevation

of temperature. Wound was dressed through a fenestra in spica at end of third week, when stitches were removed, primary union complete. Was removed from hospital to home at end of six weeks, and spica taken off at end of nine weeks, when union appeared firm, 45 degrees of free motion in the hip. Three months after the operation he could bear over half the weight of body on the limb, could walk upright; 1 inch shortening.

Present Condition.—Nine months after operation the limb is straight, motion normal, shortening 1 inch, can bear entire weight of body on limb without pain, walks with cane but can walk very well without it. No pain except on direct pressure over seat of operation.

AUTHOR'S CASE 6.—This case was reported at the St. Paul meeting and published in THE JOURNAL of Dec. 21, 1901. Sustained fracture of hip by a fall of rock while working in mines. Was seen by me and operated on 3 months later; practically the same operation as in Case 5, except in this case a bone flap was made before driving nail and but one nail was used besides the small nail for bone flap. Plaster-of-paris dressing the same; wound healed by first intention. Patient walked in three months with one inch shortening. Improvement continued until at the time of his death he could walk without cane or crutch; had 90 degrees of free and painless motion. Death 18 months after operation from intercurrent disease. Specimen obtained. Bony union firm in good position (Fig. 3).

SUMMARY.

1. I believe that the teachings and writings of surgical authors have been rather discouraging to the general practitioner on this subject.
2. That in all cases of fractured femoral neck, firm bony union and useful limbs may be anticipated.
3. That age is not a counter indication to treatment nor to obtaining bony union.
4. That the patient is best treated by reducing the fracture and immobilizing it.
5. That this is best accomplished under anesthesia and by the use of the plaster-of-paris spica.
6. That the immobilization should be continued for a long time, and three months should elapse before allowing weight on the limb.
7. That Buck's extension with weight and pulley is not sufficient immobilization to obtain bony union.
8. That the use of apparatus in these cases is expensive, hard to obtain when needed, not so efficient in immobilization, and less convenient for the patient and nurse than plaster-of-paris spica.
9. That the operative treatment in old and neglected cases has succeeded beyond all expectations and deserves a place in surgery among the radical cures for troublesome conditions.
10. That the patients who usually suffer from the accident being old and enfeebled is a good reason why the physician should make their declining years as peaceful and pleasant as possible.

Intravenous Injection of Chloral in Treatment of Varicose Ulcers.—An article in the *Gazzetta Med. di Roma* for June states that Scalzi has treated 200 patients with varicose veins or ulcers by the intravenous injection of a Pravaz syringeful of equal parts chloral hydrate and distilled water. No inconveniences were noticed in any instance. He applies a constricting bandage above. The coagulum forms so rapidly that the constriction can be removed ten minutes after the injections. If the lesion is merely a varicose vein, the chloral mixture is injected at different points in the vein; if an ulcer, the injections are made in the most swollen portions of the vein, close to the edge of the ulcer. The beneficial effects are evident in a few days and the ulcer gradually heals. Enrico, the author of the article, lauds this as the simplest and most effective of all methods of treating varicose veins and ulcers.

THE TREATMENT OF TRANSVERSE FRACTURE OF THE PATELLA BY SUBCUTANEOUS PURSE-STRING SUTURES.*

JOHN B. ROBERTS, M.D.
PHILADELPHIA.

In April, 1896, I reported[1] a case of patellar fracture satisfactorily treated with a catgut ligature carried around the fragments, in the coronal plane, making a sort of purse-string suture. This method seemed to me preferable to Barker's method, in which the ligature is introduced in the sagittal plane and traverses the knee joint and prepatellar bursa. I do not know that the method was new, but it is certainly deserving of extended use. Further experience has increased my confidence in it and leads me to advocate its adoption. It requires no special apparatus, such as Malgaigne's hooks, does not invade the knee joint or the synovial sac in front of the patella, and demands no general anesthetic. It is practically free from septic risks, allows the patient to get out of bed soon, and results in such a close union of the fragments that, even if true bony union is not obtained, the function of the limb is perfect.

Clinical experience and laboratory investigation seem to justify me in suggesting some modifications of the original procedure, which will, I believe, add to its surgical value.

The only instrument used is a stout needle five or six inches long and a strong ligature of silk, soft wire, kangaroo tendon or chromicized catgut. About a week is permitted to elapse after the receipt of the injury, in order to give time for absorption of blood and synovial fluid. During this period I keep the patient in bed on his back, with the knee extended and the limb elevated in order to relax the rectus muscle, which, by reason of its origin above the hip joint, may tend to draw the upper fragment upwards. An ice bag is applied to the knee to hasten the reduction of inflammatory swelling. If the intra-articular effusion were very great, I would not hesitate to tap the joint with a small aseptic trocar. This is probably seldom necessary.

When the purse-string suture is to be applied, the skin is sterilized and the aseptic needle thrust transversely through skin, muscle and fascia, just below the lower fragment of the patella. It is carried deeply enough to insure pressure against the bone when the purse-string is drawn tight and tied; but it is not expected to penetrate the joint cavity. The aseptic suture is drawn through the tissues by means of the needle. The needle is then inserted at the puncture of exit and thrust upwards, through the tissues, alongside of the broken patella, until its point emerges at a point a very little higher up the thigh than the upper edge of the upper fragment. The suture is drawn through this needle track. During these manipulations the two fragments are held together by the surgeon or an assistant. The needle is then introduced at the second puncture of exit and carried through the muscles just above the upper margin of the upper fragment. Its transit carries the ligature across the thigh superficially to the synovial sac of the joint. The needle is then inserted at the fourth puncture and is thrust downwards alongside of the two fragments until it emerges at the first puncture. It is pulled through this open-

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.

1. Annals of Surgery, vol. xxiv (1896), p. 229.

ing, and thus brings out the end of the suture; which by these maneuvers has been made to subcutaneously encircle the broken patella. The two ends of the thread now protrude from the same opening.

The final step is to pull upon the two ends steadily and vigorously, while an assistant holds the two fragments of the patella in close contact, and tie a firm knot. The knot slips within the cutaneous opening. If a thread of kangaroo tendon or catgut has been used, the ends are cut off short; and the ligature finally becomes absorbed. If silk or wire has been employed, the long ends are allowed to remain; and at the end of four or six weeks, the knot is divided by sharp-pointed scissors, or the wire is untwisted, and the suture pulled out of the tissues.

Surely no operation could be simpler than this. In fact, it scarcely deserves to be called an operation. During its performance, general anesthesia need not be employed. I have usually been satisfied with freezing the skin at the points of puncture. I am, however, inclined to think that there may be an advantage in thorough muscular relaxation, obtained by general anesthesia, before tightening and tying the ligature. The skiagraphs illustrating this paper have led me to this conclusion.

Figure 1.

Experimental fracture of patella made on cadaver with osteotome; surrounded by purse-string suture of wire.

Before introducing the needle, I press the two fragments together and rub them rather forcibly against each other. This is done to make sure that they can be brought into contact by the encircling suture and to endeavor to displace any ragged edges of periosteum or tendon that may have fallen between the broken surfaces. It has been asserted that the interposition of these fringes of fibrous tissue may be a cause of failure to obtain osseous union.

After the suture has been tied, the four punctures are dressed with layers of aseptic gauze, and a light encircling gypsum splint is applied from the middle of the thigh to the middle of the leg, to prevent sudden flexion of the knee. The patient is then put to bed with the limb slightly elevated to relax the rectus muscle.

The patient may get out of bed on crutches three or four days later, and go to his business, provided it does not require him to suddenly exert the muscles of the thigh. The splint will prevent flexion of the knee; but sudden jerking of the four-headed extensor of the leg might possibly displace the upper fragment.

The prevention of flexion should be maintained for seven or eight weeks; after which time, gradually increasing passive motion of the joint may be made until perfect mobility is obtained. For a time after discarding the splint, it is wise for the patient to carry a cane, lest a sudden slip or loss of balance should result in refracture from sudden undue muscular action.

It may be better to use a second purse-string suture, carried around the patella more superficially than the one already described, in order to purse up the tissues near the anterior surface of the fracture. This would, I think, have a tendency to prevent the tilting of the fragments, which is seen in recent untreated fractures and shows in my skiagraphs. In such an operation I should be inclined to tie the superficial or more central suture first. The greater separation, of the anterior, surfaces of the fragments is said to be due to the attachment of the extensor tendon and of the ligament of the patella to the anterior portion of the knee-pan. An encircling suture through the tissues at the anterior, or superficial, face of the bone would seem to be an efficient means of obviating this tendency of the fragments to gape apart.

Figure 2.

Experimental fracture made on cadaver with osteotome and then encircled by two purse-string sutures of wire.

I show skiagraphs of the two methods of operating, done on a cadaver, in which I produced fractures with an osteotome. The absence of muscular tension and synovial effusion makes the experiments inconclusive. They serve, however, to show in a crude way the methods described.

ILLUSTRATIVE CASES.

A woman was admitted to the Polyclinic Hospital on Jan. 31, 1896, with the ordinary transverse fracture of the patella. One week after the accident I drew the fragments together with an encircling purse-string suture of chromicized catgut, carried through the tissues in the coronal plane. The apposition was good as soon as the ligature was tied, though previously it had seemed impossible to bring the fragments

into perfect position by pressure of the fingers, although the patient was under ether.

Two days afterward the limb was encased in a gypsum splint from the upper part of the thigh to the foot. Before the gypsum had hardened, the assistant inadvertently let go of the foot and permitted the knee to be flexed a little, causing some pain. I permitted the patient to get out of bed and walk with crutches two days later, or eleven days after the receipt of injury. This early discontinuance of confinement apparently does no harm, and is a very great advantage in the method of treatment.

The plaster-of-paris splint was removed in four weeks, when the knee showed about a quarter of an inch separation between the fragments anteriorly. This was supposed to be due to the stretching of the catgut ligature at the time the assistant permitted sudden flexion to occur, while the gypsum splint was being applied. It is likely that there was at this moment a sudden involuntary contraction of the four-headed extensor muscle.

Figure 3.

Fracture of right patella treated at Methodist Hospital by purse-string silk suture. Taken about 15 months after accident. Use of leg PERFECT. Externally the bone feels as if bony union had occurred.

It may, it is true, have been due to the ambulatory method of after-treatment. My subsequent experience leads me to think that it was not due to either of these causes, but to the usual tilting of the fragments.

I have no notes to show how much longer the limb was kept extended and protected from flexion; but the hospital record states that she was discharged on February 20. I showed the case at the meeting of the section on surgery of the College of Physicians of Philadelphia on April 10, ten weeks after the receipt of injury, and the union was as close as mentioned above, though probably not bony.

A young man fell down three cellar steps while carrying a quarter of a barrel of beer, because a piece of projecting wood caught the edge of his trousers and threw him. He was admitted in November, 1901, to the Methodist Hospital, which he left after being under treatment nearly eight weeks, for a transverse fracture of the right patella. I treated him with a purse-string suture of silk which was removed before he left the hospital.

When examined after the lapse of fifteen months, the patella was perfectly movable and the union appeared to be bony. The man could flex the knee perfectly, but there was a grating sensation occasionally felt when I moved the joint. There was no stiffness and the leg was as strong as ever. The patient says that he can carry a half-barrel of beer upstairs and that his situation in a brewery compels him to do this sort of work constantly. I had him kneel upon the floor and found that he could rise without the least difficulty from the kneeling position. There is no difference, in power or in flexion and extension, between the two legs. The front of the right knee looks a little bit thickened so that the outlines of the patella do not show as distinctly as in the normal leg. The injured patella seems to be about one-eighth of an inch longer than the other patella. There is no pain or discomfort about the leg. The man says he notices no difference between them in usefulness or feeling. He went to work four weeks after leaving the hospital, but it was seven weeks after leaving

Figure 4.

Fracture of patella treated by purse-string suture of silk at Polyclinic. Taken before suture was removed. March, 1902. Left leg.

the hospital before he could carry heavy weights like beer kegs.

A skiagraph was taken fifteen months after treatment and showed that the union was fibrous and the fragments tilted apart at the anterior surface. This surprised me, for palpation of the knee gave the impression that the union was bony, and it was only by careful examination that the line of fracture could be made out. The fragments are not quite in contact even at the under surface of the bone; and there is evidently an osteophytic growth on the lower surface of the lower fragment. It is doubtless this roughened area that gives rise to grating during passive motion. The skiagraphic illustration shows well these imperfections in the reconstruction of the patella.

It is interesting to note that the functional integrity of the bone is complete though the anatomical contour is imperfect. This is pretty good evidence that the adoption of incision of the knee-joint, for the purpose of carefully suturing fascia and bone, is unnecessary. Such an operation is more risky to the patient than the purse-string suture and can give no better functional result than was obtained in this case.

The ideally perfect union of bone, periosteum and fascia is not worth the increased risk to the mobility of the joint and to the life of the patient.

A man, aged 40 years, was admitted to the Polyclinic Hospital on Feb. 9, 1902, with transverse fracture of the left patella. He had fallen while under the influence of liquor. Eight days later, after preparatory treatment by elevation of the leg and the application of an ice bag, I drew the fragments together with a silk purse-string suture. A plaster-of-paris splint was applied and the patient put to bed with the leg elevated to relax the rectus muscle. No inflammatory reaction followed and March 17 the silk suture was removed and the fragments found in good apposition. It was necessary to make a little incision to reach the knot of the suture, in order to cut the thread at that point and draw it out of the tissues. The man had been kept in bed all of this time with the joint immobilized. This was longer than necessary. On April 4 the patient was discharged with a light gypsum splint, to prevent sudden flexion of the joint. I have seen the patient a number of times since then, and there appears to be slight motion between the two fragments, as though the union were a short fibrous one. The skiagraph made while he was still in the hospital and before the suture was removed shows that this is really the case. There is the same tilting apart of the fragments at the anterior surface that I have mentioned as usually present.

DISCUSSION

ON PAPERS OF DRS. RUTH,* THOMSON AND ROBERTS.

DR. W. H. CARMALT, New Haven, Conn.—In the paper by Dr. Ruth I think the true principles of surgery have been carried out in that the traction is made in the direction of the axis of the bones that are broken. We are too apt to think that the femur simply goes from the trochanter to the knee and ignore the fact that the neck of the femur is at another angle. To apply the pulley to the outer side certainly appeals to my judgment and I shall try it. The question of immobilization that Dr. Thomson refers to is good so far as it goes, but it lacks in just that particular that Dr. Ruth gives us. I should like to ask Dr. Thomson about his photographs, as I see something that apparently looks like nails driven in the axis of the bone. I do not know whether that is a skiagraphic shadow or is really in the specimen. The question of fixing the bony fragments with nails is not new, and I think Dr. Senn wrote an article on this subject. As to Dr. Roberts' paper I have tried a similar plan and think it suits very nicely in certain cases. I should be the last one in the Section to say we should not strive for the very best bony union possible. You have all seen cases where there is wide separation of the fragments, with a very useful leg. I remember some years ago Dr. Bull reported some cases of fracture of the patella and one was a fireman and one a policeman who were both in active discharge of their duties. They climbed over chairs and tables and did everything that anybody would be likely to do in spite of a separation of some inches between the fragments. I do not propose to advocate any slack method of treatment, but the simple fact is that patients with wide separation occasionally have very useful legs. I do not know anything better than Dr. Roberts' suggestion, and I have tried it in one case. I believe Dr. Roberts makes a purse-string suture all around, and I have done it once in that way. I have seen it reported in two cases subcutaneously, and I like the results very well.

DR. A. H. LEVINGS, Milwaukee—Fractures of the patella are of frequent occurrence, and may lead to a good deal of disability if the fragments are not brought in close apposition. The purse-string suture of Roberts is at this time not new, as it has figured in many of the text-books, and I myself have been pleased to employ it. There are, however, certain seemingly serious objections to its general use. In these fractures the upper fragment is often tilted backward into the joint cavity, rendering accurate apposition by the purse-string suture difficult or impossible. The fractured portion of the upper fragment is often covered by the torn capsule, which also hangs into the joint, again rendering close apposition of the broken fragments by this suture difficult.

Everyone who has opened these joints has found them filled and over-distended with blood, which is either more or less coagulated and at times in a state of semi-organization. These blood clots are not unfrequently the cause of adhesions, floating cartilages, and loose bodies. I have preferred to treat these fractures by opening the joint, preferably at the end of the first week, when the lymphatic and connective tissue spaces will have become closed by adhesive inflammation, thus rendering infection much less liable. After the joint is opened by transverse incision and the fluid and clotted blood thoroughly washed out with a carbolized solution the fragments are evenly and nicely coapted by wire suture, and the torn capsule by strong catgut. At this stage there is no hemorrhage and drainage is unnecessary. I have never seen infection follow the operation, and have had occasion only to congratulate myself and the patient on the result.

DR. J. P. LORD, Omaha—I have devoted considerable attention to the treatment of fractures of the small part of the neck of the femur. Twenty-one years ago, as a medical student, I was taught by my preceptor the same principles as those mentioned by Dr. Ruth. He did not claim originality for it, and I do not know where he got it, but it impressed me, and always has, as a matter of great importance in reducing this fracture. Through all these years there has been an evolution going on in my practice in establishing for myself a method which would at once reduce the deformity and maintain reduction as well as render less likely non-union or deformity. Union takes place in the aged in other fractures with almost equal facility as in the young, and there is no longer any doubt that union will take place in the small part of the neck of the femur if immobilization is maintained. The great difficulties we have in feeble subjects is to be able to get proper appliances to maintain apposition for this result to take place. There has been a tendency all these years to simply get along with tentative treatment of these cases. I have the greatest admiration for an operator who will cut down and screw or nail the fragments together, but these cases usually fall into the hands of those who would be loath to do this operation. They are not sufficiently trained to justify them in doing so formidable an operation. We should establish such a line of treatment as will best secure the combined results. A method which has served me well is to apply Buck's extension with a wide plaster to the perineum and pad and bandage the leg to that point. Put in your foot stirrup with cord and make a loop in it so that an assistant may put it around his body, and make traction. Put a strap around the thigh and from this exert traction upward and outward by means of rope and pulley, to overcome the tendency to eversion caused by the action of the strong gluteal muscles which rotate the limbs outward and can only be properly overcome by the means described. I think that a little inversion is desirable to insure a normal result. This system keeps up constant extension and the fragments are in apposition. This lateral extension is used until the fragments are in the position they should be. And to maintain them I put a piece of board in the plaster about four inches wide and 20 inches long, 1/3 of an inch thick; this rests directly behind the trochanter, when applied to the thigh portion of plaster. This extends off from the body about six inches. The body is thoroughly padded previously, and when this board is forced in against the body its spring maintains a continuous pressure. The plaster dressing is made secure. The patient is put to bed, requisite extension is applied, and this is maintained for eight weeks. My results are from 1/4 to 1/3 of an inch shortening with absolute bony union, and no deformity nor eversion. I have only had two cases, but there is no question about the union nor the results. If this

* The paper of Dr. Ruth appeared in the issue of Nov. 29, 1902, page 1380.

treatment is carried out you should secure good results. I have perfect confidence in it.

Dr. Carl Beck, New York City—As to Dr. Roberts' paper, one point has been overlooked, namely, that the whole question of operation hinges on the degree of diastasis. In transverse fractures of the patella showing little or no diastasis, a plaster-of-paris dressing is applied best. While the displaced fragment is tightly grasped and pushed downward by the fingers of an assistant, the dressing is applied. The limb is best put in the hyperextended position, while the patient sits in bed half upright. The turns of the bandage are conducted around the pressing fingers, so that at last a wall is formed around the digital impressions, which includes the reduced fragments after the plaster sets, and becomes so firm that a return of the fragments proves to be impossible. If there is a fair amount of diastasis, the operation so well described by Dr. Roberts is advisable. But if there is considerable diastasis, wiring of the fragments can not too strongly be advocated, since the performance of this simple operation is void of danger in the hands of a surgeon who is master of the principles of asepsis. Whatever has been said of the dangers of this operation applies more to the surgical novice, who does not properly understand asepsis, than to aseptic surgery itself. When it is considered that without such operation union becomes only fibrous, and that in the course of time the originally fibrous bands become stretched by the action of the quadriceps muscle, so that active extension of the knee-joint became impossible—in other words, that the patient becomes a cripple for life—we should not refrain from exposing the patient to the trouble of this operation, which guarantees an absolute cure.

Complicated maneuvers, like boring holes into the fragments, can not be too strongly condemned, since simply conducting a large needle armed with silver wire around the fragments secures their perfect apposition. The needle must be introduced at the upper end into the quadriceps tendon above the patellar margin and through the ligamentum patellæ on the lower margin of the lower fragment. The silver wire is twisted above the middle of the fracture line, its ends protruding at last through the suture line of the integument. A semilunar incision should be made from one epicondyle to the other, just above the insertion of the ligamentum patellæ. Thus a convex flap is formed, which is dissected backward. The fractured area is then fully exposed, and the intra-articular blood extravasation can be freely reached. An ironclad principle, especially referring to this operation, is "Hands off the joint!" For the consolation of such surgeons as are afraid of the aseptic state of their own fingers it may be said that there is no need for coming into contact with any portion of the field of operation with their fingers or hands. The needle can be carried through with the aid of a needle-holder and the twisting, which in itself tends to bring the fragments together, can be done with a forceps. The blood-clots can be removed by powerful irrigation with a hot sterile salt solution.

After the suturing (preferably done with boiled formalin catgut) is completed, either an ordinary wound dressing, supported by a large moss splint, or a fenestrated plaster-of-paris dressing (the fenestra being created by holding a sterilized glass over the wound) is applied. The wire suture is carefully removed after three weeks. Then the knee is well immobilized for two or three weeks longer, and the patient is allowed to walk about in this dressing. The wire must be very strong, for there is risk of its breaking if the patient be restless.

Dr. T. J. Maxwell, Keokuk, Iowa—I am responsible for the technic described in Dr. Ruth's paper. In the winter of 1870 I was called to see a lady, aged 52, who had fallen, striking on the right trochanter. She was rendered helpless, unable to arise or use that leg. She was carried into the house and placed on a pallet on the floor. Examination showed shortening of right leg two inches, eversion of foot and leg, the upper end of femur turned on the axis of shaft, not describing an arc, as is normal. There was great tenderness on movement, crepitation developed on extension with rotation. The patient was thin in flesh and the fingers grasping the trochanters could easily palpate their entire circumferences to the junction of the neck, thereby making the diagnosis of fracture of the neck complete.

I dressed the fracture by the application of a long side splint (Day's). It made extension sufficient to bring the leg to the right length determined by measurement. This dressing was retained for one week. Though the leg was the right length, there was flattening of the hip and constant pain. I knew the bones were not in coaptation. Nature had no chance to repair the injury. At the end of the week I determined to change my dressings, so that the fragments could be placed in apposition. The body of the patient was made the counter-extending force, by elevating the right side of the bed twelve inches at the foot, four inches at the head of bed on right side. The left side of bed, at the foot, was raised eight inches. Therefore the body gravitated toward the head and left side of bed. Extension (longitudinal) was made by the application of adhesive straps to either side of thigh and leg from body to ankle. A cord was attached to these straps. This cord was carried over the pulley at the foot of the bed, and a weight of about fifteen pounds, or enough to keep the leg the proper length applied. The hip being flat, I next applied a band close to the body, around the thigh. To this band was attached another cord, which was carried over a pulley at the side of the bed (this pulley was so placed that it was about eight inches higher than the body, and opposite the anterior superior spine of the ilium). Sufficient weight was attached to this cord to draw the trochanter upward, forward (as to body erect) and outward, until it was exactly as prominent as the uninjured one. This form of application relieved all pain and comfort was secured, as it did in all the subsequent cases treated in like manner. At the end of six weeks the union was complete and perfect, as far as one could judge from a careful examination and movements of joint. There was no shortening and the leg was functionally perfect.

Dr. Roberts, in his paper, refers to his preceptor having gained some knowledge of the lateral extension, from some source, unknown to him (Dr. Roberts). In answer to that I may be allowed to suggest that he likely got it from a paper I read on the subject, reporting my first case, at Galesburg, Ill., before the Military Tract Society, during the summer of 1870. Or he might have heard the paper read before the Illinois Medical Society during the spring of 1881.

The numerous cases reported in Dr. Ruth's paper are accounted for by the fact that I have taught that method in the Keokuk Medical College for the last seventeen years. The students graduating from that institution practice the method and report their cases to Dr. Ruth or myself. The method is, 1, rational; 2, painless; 3, simple and easily applied. 4. It is inexpensive and always at hand. 5. Forty and more successful cases at least commend it for trial.

Dr. H. M. Sherman, San Francisco—There is, I think, one point in connection with femoral neck fractures that needs always to be mentioned, and that point is the necessity for gentleness in the examination. This is for the conservation of any slight, or even fairly firm, impaction. The diagnosis should be made rather by measurements than by manipulation, and with this method I have obtained a satisfactory amount of success. As to the demonstration of Dr. Ruth, it is comparable to that marvelous demonstration made by Dr. Allis in Philadelphia, of dislocation of the hip, and I can not pay it a much higher compliment. I want to ask Dr. Roberts what he does with the infolding capsule in cases of fracture of the patella. In the few cases in which I have done it I have been pleased with Stimson's method of suture of fibrous tissues to coapt the fragments.

Dr. John B. Roberts, Philadelphia—In answer to Dr. Sherman I may say that it is my practice before I put the purse-string suture around to rub the surfaces of the broken bone together. I am not sure that I get bony union; indeed, I think that probably very often I do not. I have skiagraphs that show I do not at times. My impression is that it does not make any difference whether the union is bony or fibrous if it be close and strong. It is not necessary to subject your patient to the danger of an arthrotomy when you can get a good union

by some such simple method as this. It seems to me that it is better for most of us to treat transverse fractures in this way. As to the fractures of the neck of the femur, I may say that I have been very much interested in the subject. All the illustrations presented seem to be fractures of the base of the neck of the femur; which are the fractures of that part which very frequently unite if they were given the chance. None of the specimens shows union of fracture through the small part of the neck. I have great respect for Dr. Scudder, but I think his book is very old fashioned. It does not seem to me to be up to date in the treatment of fractures. Therefore, I do not altogether agree with the speaker, who lays great stress on its statements as to these factures. Dr. Maxwell's fracture seems to be a fracture at the base of the neck.

DR. R. H. GIBBONS, Scranton—Dr. Thomson has not referred to the operation of Dr. Davis of Philadelphia. I do not think Dr. Thomson does rightly to adduct the limb. The apparatus should be applied as has been mentioned by Dr. Ruth, and Buck's extension or some other form of extension should be employed. I think two lines of traction laterally and longitudinally as recommended by Dr. Maxwell should be applied. Dr. Frank H. Hamilton first suggested the use of plaster in these cases, fracture of the femur at the neck or elsewhere, and Dr. Sayre later recommended it. Lateral extension and the application of plaster were recommended, too, by Dr. A. M. Phelps. Dr. Davis recommends the anterior incision, instead of Gillette's, as used by Dr. Thomson, which is similar to Mr. Barker's of England and that of the late Dr. King of Pittsburg, Pa., in exsection of the head of the bone for diseased condition thereof. Davis says about his method of operation, that after exposure of the neck through the anterior incision, through which the capsule is not only opened, but partially cut away by scissors, through which opening a finger is passed in order that the line of osseous separation through the neck is felt, and by means of which feeling he is enabled to direct the movements of the link by his assistant to obtain reduction of the fracture and apposition of the line thereof, then through an opening over the trochanter a silver nail or screw is to be passed in line crossing the line of separation, the nail passing through the reduced fragments from the trochanter into the neck, and this without turning up the trochanter by Gillette's method, which is a weak point to his plan, otherwise quite a perfect and original operation.

DR. W. T. ECKLEY, Chicago—I wish to call attention to an anatomic principle in the Maxwell-Ruth method that has a precedent in the physical law of projectiles: projectiles follow the line of greatest traction, the point of least resistance or the resultant of the two. In this method of treatment the resultant of lateral and longitudinal traction falls in the long axis of the neck of the femur because the external rotator muscles are physiologically immobilized. A treatment that secures physiologic repose by immobilization of those anatomic factors which, under less successful methods, defeat the objects of the procedure, is certainly "anatomic treatment," and Drs. Maxwell and Ruth are to be congratulated on harmonizing a principle of philosophy as old as medicine itself with modern treatment of fractures of the neck of the femur.

DR. RUTH, in closing—There is a great deal that might be said if time permitted. Mention has been made of impacted fractures. I had such a case in a person 74 years of age. It began to loosen in four days. The shortening was then manifest, which did not appear at first. There was a final shortening of a quarter of an inch. Lateral traction is indispensable, but the apparatus is not difficult to apply. It is comfortable to the patient, and can be raised to the sitting posture. After the first two days in nearly all of these cases they will flex the sound leg and raise the hips themselves. The bedpan is readily passed under them. Objection has been made that none of these fractures were through the narrow part of the neck, but I here present a specimen of such a case fractured at 72 years of age, used for twenty years thereafter. The leg has given the patient good service for twenty years and the line of fracture could scarcely be distinguished on the outer side. It has been hinted that this was an impacted fracture, but there was two inches of shortening, as testified by Dr. Maxwell. The man had slight eversion of the foot the rest of his life, which also showed that a fracture had taken place. I have purposely picked out the line of union in specimen two, which was treated for only four weeks, to show it more plainly in cut, and the union was very strong for the time. Dr. Jenkins, who had charge of the case for a time, is present, and can vouch for the accuracy of my observation. You can tell from the specimen what had happened, but no one could determine that there had been a fracture had the patient lived for a year. I presented a specimen from a case in a patient 81 years old, and the result enabled the man to work without inconvenience for six months, when he finally died of sunstroke. As to the plaster cast it will do in a great many cases, but every one of you know that it is only about 48 hours after placing a cast that the tissue begins to diminish in size, and your cast is loose. You can not, therefore, maintain perfect extension with a plaster cast nor can you influence the rotators and absolutely prevent eversion and posterior displacement. I feel like complimenting Dr. Thomson on his results. The only thing that makes me feel badly is that the gentleman did not use the anatomic method. If we have the next meeting in the neighborhood of Iowa we will show quite an array of cases that will walk without a limp or halt.

DR. THOMSON, closing—I am afraid I have been rather misunderstood. I am sorry Dr. Carmalt did not understand that the specimen on the board was a case repaired during life. There was no diagnosis made on this man at the end of three months after the accident, and until that time he was bedridden. The operation is described in my paper, but I did not have time to read it. As to the material I have never used anything but solid silver nails. They do not corrode, and I think they are by far the most satisfactory. As to the patient who walked around the hall—my second operative case—and limped a little, this man lay for 18 months, or sat in a chair with an ununited fracture of the neck of the femur that had not been diagnosed. It is nearly nine months since his operation. I believe he will walk as perfectly as any man can do, in time. As to plaster of paris versus apparatus I believe that the surgeon who has to wait in the course of his treatment for a skilled mechanic to fix up an apparatus is being handicapped, and I think we should be able to do this work ourselves. Dr. Gibbons has said I was expert in the use of plaster of paris, but there is not a man in this room who could not make as good a plaster cast as the one presented here in fifteen minutes, for 25c. As to its holding on and getting loose I will guarantee that if it is properly applied it will stay there indefinitely. As to reduction of the fracture I did not have time to read this, but it is described in my paper. The same principle as Dr. Ruth teaches about reduction is taught in the reduction under anesthesia. We reduce our fractures on the same principle as Dr. Ruth teaches, and then put it up permanently and it unites.

Schweninger's New Post.—Our German exchanges are continually commenting on Schweninger's career. He was recently appointed professor of the history of medicine, which has called forth a formal protest from the National Society for the Study of Medical History. He has since then had a polyclinic for internal diseases organized for him at the Charité. There are already two connected with the institution and another in the vicinity, so the necessity for a fourth official polyclinic is not apparent. He is still at the head of a large public hospital, and besides his duties as professor of the history of medicine and chief of the new polyclinic, is docent for general pathology and therapeutics. He is not a trained physician, but was Bismarck's medical adviser, as has been previously mentioned in THE JOURNAL, and was for a long time professor of cutaneous diseases. In a public lecture a year or so ago he made the statement that he would leave a certain question to students of the history of medicine, for which he confessed he had "neither talent nor training." This quotation has been going the rounds since his appointment to the chair of history.

UNCINARIASIS OR ANKYLOSTOMIASIS

WITH THE REPORT OF A CASE.

JOSEPH A. CAPPS, M.D.
INSTRUCTOR IN MEDICINE, RUSH MEDICAL COLLEGE.
CHICAGO.

VARIETIES OF UNCINARIA.

The uncinaria or hook-worm belongs to the family *Strongylidæ*, subfamily *Strongylinæ*, genus *Uncinaria*. As the name indicates, the parasite is characterized by a dorsal curvature of the anterior end of the body resembling a hook. The mouth is armed with teeth which have great penetrating power. The worms vary from one-half inch to an inch in length and are peculiar in that they live by sucking blood from the host.

The parasite is not confined to man, but exists in many animals. *Uncinaria canina*, according to Stiles,[1] is common in Washington, D. C., and has caused among pups in some communities the death of over 25 per cent. It also occurs in cats. *Uncinaria stenocephala* is found in dogs, foxes and other animals. *Uncinaria trigonocephala* occurs among the sheep in Texas and has killed 25 to 50 per cent. of certain flocks. *Uncinaria radiata* was described by Stiles in the cattle of Texas. *Uncinaria Lucasi* produces a mortality of 17 per cent. in the seal pups of Alaska.

DESCRIPTION OF THE SPECIES INFECTING MAN.

The two species of hook-worm which infect man are *Uncinaria duodenalis* (Dubini), or the old-world hook-worm, and the *Uncinaria americana*, recently identified by Stiles as a new-world species. A fact of great importance to the physician is that the species found in animals has not been observed in man, and the human species is not known to infect lower animals.

As the *Uncinaria americana* probably conforms in its life history to the *Uncinaria duodenalis*, the same description will apply to both forms. In the fresh feces are seen the eggs in various stages of segmentation. No larvæ are present until the ova have been exposed some time to the air under proper conditions of moisture and heat. It is the lack of air which prevents the development of larvæ within the intestine. With favorable culture surroundings outside of the body the larvæ emerge from the ova in 24 to 36 hours. The youngest rhabditiform embryos are from .2 to .3 mm. long and have a spindle-shaped esophagus ending in a rounded stomach, that contains tooth-like structures. The embryo takes up nourishment, and after casting the skin several times and undergoing certain anatomic changes, becomes full grown within eight days. It is then from .6 to .8 mm. in length and about .024 mm. in breadth.

This mature larva is exceedingly active and has a much greater tenacity of life than the younger forms. If the temperature is not below 20 C., and if the culture medium is moist, it will remain alive and active for weeks or months, but no further development occurs outside the body. It is with the larvæ, not with the ova, that man becomes infected. After being swallowed by the host, the larva seizes on the intestinal mucosa, sucks blood for nourishment and begins a new period of growth. Within two weeks the parasite again casts its skin, the sexual organs become differentiated and developed, and the anterior extremity acquires a buccal capsule with teeth. Five weeks after infection the worms are ten to twenty times the length of the full-grown larvæ.[2] The largest larvæ are scarcely visible to the naked eye, while the adult worm, 6 to 14 mm. (¼ to ¾ in.) in length, is easily seen. The presence of mature worms within the intestine is manifested by the appearance of eggs in the stools.

The shortest possible time necessary to the completion of the cycle of development from the eggs through the larval state outside the body, through the sexual ripening within the body, to the production of eggs again, is from 5 to 8 weeks. But this period is usually much longer because of the indefinite duration of the parasite in the larval stage.

NARRATION OF CASE.

The following case in the Cook County Hospital was in the service of Dr. James B. Herrick, through whose interest and kindness I am enabled to present this report:

Previous History.—G. L., 52 years of age, was a carpenter by occupation and a native of the United States. There was nothing in the family history of any significance. He enjoyed excellent health until the year 1879, when he went to Panama to work at his trade. While there he suffered from repeated attacks of malaria of both quotidian and tertian types.

Two years ago the patient was first taken ill with sudden gastro-enteric symptoms. At that time he was employed on the Chagres River, where he handled lumber and logs that were often covered with mud. He recalls that he frequently sat down to luncheon without previously having washed his hands. The earliest complaints were of an aching pain in the upper belly, loss of appetite and weakness. There was no nausea nor vomiting. The bowels were irregular, at one time loose, at another constipated. Later he became short of breath and dizzy from any unusual exertion and had palpitation of the heart.

In January, 1901, he sailed from Panama to New Orleans, where he was in a hospital under treatment for 15 months. There the anemia was so pronounced and so intractable to iron and arsenic that the diagnosis of pernicious anemia was made.

April, 1902, he went to Iowa, but the anemia progressed steadily until he was too weak to move about.

September 9 he was admitted to the Cook County Hospital, complaining chiefly of pains in the belly, weakness, dyspnea and palpitation. After sitting or standing the feet would swell. Frequently he had spells of dizziness and faintness. Patient says that he would occasionally develop a moderate fever and at such a time the epigastric pain was worse. The appetite was poor. The bowels required a laxative. There was never any hemorrhage from the nose, intestine or skin. Vision was good. A gradual moderate loss of flesh had taken place.

Status presens: Man of medium build; skin of a lemon-yellow color. Fatty layer fairly well preserved. Sclerotics bluish and muddy. Lips and mucous membranes almost bloodless. Palpable arteries moderately thickened. Pulse of large volume, soft and compressible, low tension, with a decided water-hammer character. Lungs negative.

Heart dulness extended to the left nipple line, to the upper border of the third rib above, and to the right edge of the sternum. The impulse was forcible and diffuse. Over the apex was a systolic blow transmitted to the anterior axillary line. A louder bruit of a different pitch was audible over the mitral area and the base. The pulmonic second sound was louder than the aortic closure.

The spleen was not palpable though its area of dulness was enlarged. The liver was not felt. The epigastric and umbilical regions were tender to pressure. Knee-jerks present, but not prompt.

Temperature 98.6, pulse 90, respiration 20. Urine 1.015—no albumin—no sugar and no casts.

September 11, blood examination showed hemoglobin 18 per cent., reds 2,576,000, whites 6,600. No stained preparations were made.

September 15, gastric contents were expressed one hour after a test meal of tea and toast. No free HCl present, no lactic acid.

September 23, blood examination, hemog. 17 per cent; reds, 2,280,000; whites, 6,000.

October 20, blood examination, hemog. 12.5 per cent.; reds, 843,000; hematocrit, 980,000; whites, 4,500; color index, .80; volume index, 1.17. The differential count showed: small mononuclear, 10 per cent.; large mononuclear, 11 per cent.; polymorph. neutrophile, 66 per cent.; polymorph. eosinophiles, 13 per cent., no rouleaux formation; no nucleated red cells; poikilocytosis marked; polychromatophilia marked.

The presence of pronounced eosinophilia in a case of grave anemia made us strongly suspect the existence of an intestinal parasite so that the stools were examined frequently. The earlier specimens of feces were watery from the rectal injections employed and were therefore not easily studied. In a formed movement, however, the ova were found in large numbers. These eggs corresponded accurately in dimensions to those of *Uncinaria duodenalis*, measuring about 56 microns in length and 34 microns in width.

Subsequently the eggs of *Trichocephalus dispar* were found in small number by Dr. J. L. Miller. Charcot-Leyden crystals were present in some preparations, absent in others. Coverglass smears of feces hardened in alcohol and ether were stained with hematoxylon and eosin and eosinophilic granulations demonstrated. These granulations, like the Charcot crystals, were never numerous as is so often the case in ankylostomiasis.

The eggs were successfully cultivated and the larvæ brought to mature development. These experiments will be described later.

November 6, examination of the blood gave:

Hemoglobin 11 per cent.; reds, 748,000; hematocrit, 915,000; whites, 5,600; color index, 88 per cent.; volume index, 122 per cent. Differential count: small mononuclear, 15.8 per cent.; large mononuclear, 6.8 per cent.; polymorph. neutrophile, 70.2 per cent.; eosinophile, 7.6 per cent.; eosinophilic myelocytes, .2 per cent.; mast cells, .4 per cent. Poikilocytosis and polychromatophilia marked. Coagulation time, 5 minutes.

Previous to this examination the patient had taken thymol in small doses and it is not unlikely that many parasites were swept away and lost in the stools. The diminished eosinophilia and the smaller number of eggs found in the stools thereafter lend support to this assumption.

History in Hospital.—Treatment on the whole was unsatisfactory because of the profound weakness of the patient and the irritable condition of the stomach. A persistent nausea set in that interfered with stomach feeding and made the administration of thymol ineffective and even hazardous. Nutrient and salt enemata were resorted to, but the vomiting persisted until the patient succumbed on November 13.

During his stay in the hospital the most conspicuous symptom was epigastric pain of a dull nature at first, subsequently colicky. In the last two weeks this pain became continuous and was accompanied by great tenderness over the epigastric and right hypochondriac regions. The liver mass extended at this time about 2 inches below the costal arch and the tenderness on pressure was as great as that seen in hepatic abscess.

The bowels, as a rule, were constipated and required rectal enemata. The temperature was usually normal and ranged between 98.5 and 99.5 F. A tendency to hemorrhage was nowhere to be seen except from the intestinal tract. The feces gave the Prussian blue reaction for iron.

The examination of the eye grounds was twice carried out under difficulties. No retinal hemorrhage was apparent.

The blood findings throughout were of a most suggestive nature. An anemia at first of the secondary type, progressing until it corresponded in most respects to a primary pernicious anemia. The individual corpuscles grew larger and held an ever increasing amount of hemoglobin, the color index rising from 38 to 88 per cent. and the volume index reaching 122 per cent. The poikilocytosis was sufficiently outspoken, as well as the polychromatophilia, for a primary anemia. The scarcity of nucleated red corpuscles and the entire absence of megaloblasts is unusual in the primary pernicious form, yet some such cases have been reported. What convinced us that the anemia was not of the usual primary type was the eosinophilia of 13 per cent., for in the primary disease the eosinophiles are rarely increased. On the other hand, the uncinariæ and most of the other intestinal parasites are characterized by an increase in the eosinophilic cells.

Autopsy.—The postmortem examination was made November 13 by Dr. Harris, resident pathologist of the hospital. His report is as follows:

Body is that of a fairly well-developed and fairly well-nourished man 162 cm. tall. Postmortem rigidity and lividity present. There is a scar ½ cm. long on left arm, some edema of lower extremities. Paniculus adiposus well preserved and of a light yellow color.

Abdominal Cavity.—Diaphragm reaches to the fifth rib on the right side and to the sixth on the left. Some free straw-colored fluid in peritoneal cavity. Omentum extends down to the pelvis over the intestines and contains a considerable quantity of fat.

Pleural Cavities.—Some firm fibrous adhesions at right apex. About 1,000 c.c. clear straw-colored fluid in right pleural cavity, about 250 c.c. in left. Lungs do not meet in median line.

Pericardial Cavity.—About 500 c.c. of straw-colored fluid in the pericardial cavity. This fluid contains a few fibrinous flocculi. The pericardium is thin and surface is smooth.

Tongue, pharynx, larynx, not examined. Thymus absent. Esophagus and trachea negative.

Lungs.—Left lung smooth externally, marginal emphysema, crepitates throughout, floats in water, cut surface smooth, pale and drips fluid. On the diaphragmatic surface is a caseated nodule 8 mm. in diameter. Right lung—with the exception of the caseous nodule corresponds to the description of the left. Both lungs are quite free of pigment and weigh 2,870 gms. Peribronchial lymph glands are negative except for anthracosis.

Heart.—Cavities are quite empty, left ventricle contracted, aortic and pulmonary semilunar valves are competent, read by water test. Some fibrous thickening at the base of the aortic valves. One of the valves has a small fenestration 3 mm. long. Pulmonary valves show no changes. The mitral orifice admits three fingers and the valve shows a small amount of fibrous thickening, especially near the free borders. The tricuspid orifice admits five fingers; the valves show no changes. The left ventricle has an aberrant corda tendina extending from septum to left wall. Ventricular wall measures 16 mm., right ventricular wall measures 5 mm. Heart muscle is firm and very yellow, but not mottled. Heart weight, 300 gms. There is a slight increase of the subepicardial fat. There are a few atheromatous patches in the ascending aorta.

Spleen.—About ½ larger than normal, capsule is smooth, parenchyma is quite firm; Malpighian bodies prominent; there is an evident increase of connective tissue. The organ weighs 225 gms.

Kidneys.—Right weighs 175 gms. Section pale, cortical markings not well seen, relation between cortex and medulla is normal, capsule strips readily, pelvis is normal. Left kidney weighs 135 gms. Answers to the description of its fellow.

Ureters, bladder, testicles and adrenals present no abnormal appearances.

Liver.—Extends 4 cm. below costal arch, capsule smooth and glistening—presents yellowish mottled appearance. Cut surface mottled yellow and red, lobules well seen. Liver cuts with decreased resistance. Weighs 1,600 gms. Bile ducts patent, bile dark brown, no concretions. Pancreas shows no changes.

Stomach.—Of normal size, externally is normal, mucosa is covered with much grayish yellow mucus, no parasites.

Small Intestines.—External appearance normal. Intestines contain a large amount of very tenacious mucus. In the duodenum was found one hook-worm. One hundred and fifty were found in the jejunum and upper part of ileum, being most numerous in the upper and middle jejunum. None found in last 18 inches of ileum. They were very adherent, and were in the proportion of about four females to one male. At point of attachment of some of the parasites was found a small ecchymotic spot and scattered along the rest of the mucosa a few other ecchymotic spots were seen—possibly points of previous

attachment. The mucus in places was blood-stained. Mesenteric glands were enlarged and of a pinkish color. Appendix lies in false pelvis to the outside of the psoas muscle and behind cecum—bound down by fibrous adhesions and curled at its tip.

Spinal Cord.—Shows no microscopic changes.

Bone Marrow.—Removed from femur. Marrow is yellow and very fatty. At two points it had a reddish color, but was even here practically all fat.

ANATOMIC DIAGNOSIS.

1. *Uncinaria duodenalis* of small intestine. 2. Ecchymosis of intestinal mucosa and hemorrhage into intestinal lumen. 3. General anemia and edema of dependent portions of body. 4. Bilateral hydrothorax. 5. Hydropericardium. 6. Edema of lungs and caseous tuberculosis of lower left lobe. 7. Slight atheroma of aorta. 8. Fatty degeneration of heart and liver. 9. Aberrant chorda tendina. 10. Passive congestion and fatty degeneration of liver. 11. Chronic interstitial splenitis.

HISTORICAL.

So much has been written of late years concerning the history of this disease in the old world that I will make mention only of the more important data.

The affection was first satisfactorily described by Piso (1648) in Brazil. During the eighteenth century it was observed in Guadeloupe by Labat (1748), in St. Domingo by Chevalier (1752), in the Antilles by Dazille and Bason (1776), and in Jamaica by Edward (1790).

Dubini[3] of Milan was the discoverer of the parasite in 1838, and Siebold (1845) classified the nematode in the family *Strongylus*. Griesinger,[4] in 1854, and Wucherer,[5] in 1872, demonstrated that the widespread disease known as "Egyptian chlorosis" was caused by this parasite. In 1877 Grassi[6] and others established the fact that the anemia of brickmakers, long known in Italy to be of an epidemic nature, was a form of uncinariasis. It seems altogether probable that the Italian laborers carried the infection to the St. Gothard tunnel and caused there the fatal outbreak of 1880.

Since then the hook-worms have been observed in nearly all European countries, in Japan, Asia, Australia, India, South America and the United States. Among the names given to the disease are brickmakers' disease, geophagia, cachexia Africana, tunnel disease, miners' disease, mal d'estomac, ankylostomiasis, and more recently, the designation which is perhaps preferable, uncinariasis.

Of especial interest is the appearance of the malady in our own country. Clinical descriptions of the disease have been given by Chabert in Louisiana (1820), Duncan in Alabama (1849), and Lyell in Georgia (1849). Herff[7] also describes a case in Texas seen in 1864, where worms resembling uncinaria were found in the duodenum. Belfield[8] was one of the first to identify the hook-worm in America. His specimens were taken from the intestines of cats dying of anemia. They were sent to him by Dr. Gelbach of Mendota, Ill.

CHRONOLOGICAL LIST OF CASES.

This list reviews in chronological order the cases which have been observed in man in the United States:

I. Blickbahn[9] (1893): One case, a brickmaker, seen in St. Louis. Probably infected in Germany. Profound anemia. Eosinophiles increased. Eggs and worms observed.

II. Möhlau[10] (1896): From Buffalo, N. Y. A brickmaker who acquired the disease in the same locality. Diagnosis from eggs. Anemia.

III. Ibid. (1896): From Buffalo, N. Y. A farmer. Probably infected in region of home. High grade anemia. Parasites and eggs expelled by high rectal douches. (No mention is made of a previous administration of an anthelmintic.)

IV. Ibid. (1896): From Buffalo, N. Y. A stone cutter. Disease contracted from Italian companions in brickyard. Anemia. Eggs of *Uncinaria duodenalis* and of *Tenia solium*.

V. Ibid. (1896): From Buffalo, N. Y. A boy who had suffered from a fever resembling typhoid. Infection probably in Buffalo.

VI. Ibid. (1897): From Buffalo, N. Y. A bricklayer, who brought the parasite from the St. Gothard tunnel. Anemia. Diagnosed by eggs.

VII. Tebault[11] (1899): A case in New Orleans; developed in that city. Pernicious anemia symptoms. Both ova and parasites seen.

VIII to XI. Ashford[12] (1900): Four cases at Glen Island, N. Y. All were natives of Porto Rico who had been in the United States only a few months. Anemia in all. Eggs and worms found. Species, *Uncinaria americana*.

XII. Dyer[13] (1901): A case in a woman in St. Louis. Source of infection not stated. Marked anemia. Diagnosis from ova.

XIII. Allyn and Behrend[14] (1901): In Philadelphia. A boy, who brought the disease from Italy. Anemia of high degree. No eosinophilia. Ova and worms found.

XIV. Gray[15] (1901): A native of Virginia. Disease contracted in the state. Anemia. Eggs and worms demonstrated.

XV. Schaefer[16] (1901): In Texas. Infection occurred in Mexico. Anemia. Parasites and eggs seen in stools; also *Tricocephalus dispar* eggs.

XVI to XXIII. Smith[17] (1901): In Texas. Discovered the eggs in eight university students at Galveston. The parasites were obtained in one instance and were of the species *Unc. americana*.

XXIV. Boggess[18] (1901): In Pennsylvania. Disease imported from Italian brickyard. Anemia of pernicious type. Ova and parasites observed. *Tricocephalus dispar* ova also present.

XXV. Yates and Hall[19] (1901): In Maryland. A sailor, who brought the disease from Mexico or some other tropical country. Anemia. Eosinophilia. Diagnosed postmortem by ova and worms.

XXVI to XXVIII. Boston[20] (1901): Three cases in Pennsylvania, one a student. All brought the infection from Porto Rico.

XXIX. Claytor[21] (1902): Reported the affection in a farmer in Virginia. Anemia profound. Eosinophilia. Both ova and parasites obtained. Species, *Unc. americana*.

XXX. Greene[22] (1902): In New York. A sailor, infected either in Brazil or Florida. Diagnosis from eggs.

XXXI-XXXII. Hemmeter[23] (1902): In Baltimore, Maryland. Two cases, a soldier and a sutler, both from Porto Rico. Eggs and worms seen.

XXXIII. Herrick[24] (1902): In Washington, D.C. Subject was a soldier from the Philippines. Extreme degree of anemia. Eosinophilia pronounced. Eggs and worms both demonstrated. Species, *Unc. duodenalis*.

XXXIV to XLVI. Harris[25] (1902): In Georgia. A farmer, native of Georgia, never out of the state. Anemia. No eosinophilia. Eggs and worms detected. Species, *Unc. americana*.

XLVII. Ibid.[26] (1902): Thirteen other cases in Georgia, all farmers. In one case the disease was brought from Florida, in another from Alabama. The remaining eleven were infected in Georgia. Anemia of varying intensity. Diagnosed by presence of eggs. Species, *Unc. americana*.

XLVIII to L. Moffitt:[27] Three cases in California, two coming from Mexico and one from the Philippines. Diagnosis by ova.

LI. Capps: The writer's case herewith reported, from Chicago. Infected in Panama. Pernicious anemia symptoms. Eosinophilia. Both eggs and parasites observed. Species, *Unc. duodenalis*.

SUMMARY OF CASES.

In all there have been 51 cases reported. A glance will show that the seaboard states have suffered most. New York leads the Atlantic coast group with 10 cases; then comes Pennsylvania with 5; Maryland with 3; Virginia with 2, and the District of Columbia with 1. Georgia exhibits the largest number in the south (14),

Texas follows with 9 cases. Louisiana has but one. California claims 3 cases on the Pacific coast. The inland states are represented by Missouri (2) and Illinois (1) alone, and it should be emphasized that in the two states last named the disease was imported in every instance.

A more important inquiry concerns the localizing of the regions in this country where the disease is endemic. With the exception of 3 cases originating in New York and 2 in Virginia, the infected areas are situated in the states adjoining the Gulf of Mexico, viz., Georgia, Texas, Alabama, Florida and Louisiana.

This fact becomes significant when it is stated that of the imported cases 9 came from Porto Rico, 4 from Mexico and 1 each from Panama and Brazil respectively. The Philippines contributed 2 cases, Italy 3, Switzerland and Germany 1 each.

The prevalence of uncinariasis in the South and in the West Indies is far greater than the published cases would indicate. Competent observers believe that the "clay-eaters" of the South and many of the ill-nourished anemic inhabitants are subjects of the malady.*

PREVALENCE IN THE PHILIPPINES AND WEST INDIES.

Uncinariasis is a common disease in the Philippines, according to the reports of our army surgeons.

From the 8 cases observed in Cuba this year by Guiteras,[38] we may reasonably believe it to be a common affection also among the Cuban natives.

Ashford believes that the complaint is widespread in Porto Rico. He selected 20 cases of so-called "tropical anemia" and found the ova of uncinaria in 19.

SPECIES OF PARASITE IN THE NEW WORLD.

Less than a year ago Stiles[28] discovered that the hook-worm found endemic in Texas, Virginia, Georgia and the West Indies was of a different species from the old-world type, and named it *Unc. americana.* This species is characterized by an anteriorly situated vulva, a dorsal conical tooth, and in the caudal bursa of the male by a bipartite division of the dorsal ray.

Most observers have not attempted to differentiate these varieties. The case of Allen and Behrend, which came from Italy, was infected with the *Uncinaria duodenalis,* as might be expected. Herrick's case from the Philippines was also *Unc. duodenalis.*

My own case, from Panama, I first described as the old-world species and subsequently this opinion was confirmed by Dr. Stiles, to whom I forward specimens. It is surprising to find the new-world type in the West Indies and the old-world species in Panama. Are we to consider the Panama region as contaminated by the foreign canal workers, or is the duodenalis endogenous on this continent as well as *Unc. americana?* The question can not be definitely answered at present, but it seems not unlikely that the duodenalis was imported to Panama by Italian laborers employed on the canal. Light would be thrown on this question by an investigation of the species occurring in Mexico and the countries adjacent to Panama.

CULTURE EXPERIMENTS.

The conditions necessary for the hatching out of eggs and the growth of larvæ are:

(*a*) A suitable culture medium. The feces have proven better than artificial media.

(*b*) Moisture. The larvæ die rapidly if the medium is allowed to dry. The ova develop best in a soft medium without too much water.

(*c*) The temperature should be not above 37° C. and not below 20° C. Between 25° and 30° C. the growth is most rapid. High temperature and freezing destroys both eggs and larvæ.

(*d*) Air. Without a supply of oxygen the eggs do not hatch. Hence the outer layer of a culture shows many embryos, while the inner portion may contain eggs only.

The following experiment was tried: A bottle filled with feces was tightly corked and kept at a temperature of 27° C. for two weeks. No larvæ were present. The same specimen was replaced in the incubator with the cork removed under the same conditions of moisture and temperature. Within 46 hours embryos could be seen in great numbers.

At a temperature of 27° C. the embryos were developed to maturity. The structural changes incident to growth and the several stages of shedding the outer cuticle (ecdyses) could be easily followed. I was particularly impressed with the voracious feeding of many younger forms. One could see particles of matter carried down swiftly from the mouth to the bulb-like end of the esophagus, impelled by a vibratory sucking action. Within the bulb the material was macerated by the claw-shaped teeth and forced downward in the alimentary canal, where it was finally expelled from the anus by a contraction of the lower extremity. The complete process from ingestion to expulsion occupied less than one minute and illustrates the surprising blood-sucking capacity of the parasite. Larvæ eight weeks old are still present in our cultures.

I am at present feeding the living embryos to cats and dogs in an attempt to infect them. Previous experiments along this line, however, have been unsuccessful.

MODE OF INFECTION.

Man contracts the disease by swallowing the living larvæ. Both food and drinking water may carry the contagion, but perhaps a more common method results from uncleanliness of the hands. The subject gets the hands covered with the larvæ-contaminated mud, and in conveying food to the mouth ingests the parasites. In one drop of mud there may be dozens of embryos, so that a few exposures of this nature are sufficient to produce a severe infection. Among the "clay-eaters" the danger of infection is obviously very great.

The soil itself may owe its contamination to the careless deposit of feces from an infected individual. Thus one subject may cause an epidemic among workers in clay that was previously free of larvæ.

Looss[29] has proven that the larvæ may also enter the body through the epidermis. Bentley,[30] experimenting along the same lines, has discovered that the "ground itch" of coolies is set up by an invasion of uncinaria larvæ into the skin.

SYMPTOMS.

The symptoms fall into two general groups:

(*a*) Gastrointestinal. Severe colicky pains in the abdomen, nausea and vomiting and diarrhea occur often in the acute forms, less frequently in the chronic.

(*b*) Those arising from anemia of varying intensity. Most characteristic are the cases with a profound anemia who suffer from dizziness, dyspnea, hemorrhages, edema and exhaustion.

Many individuals who harbor a small number of worms, suffer, doubtless, from vague symptoms of malaise, indigestion and malnutrition. Still others do not consider themselves ill.

* See Editorial, p. 36, and Society Report, p. 48, in this issue.

DIAGNOSIS.

1. The *occupation* is often suggestive. Workers in dirt and clay, in brickyards, tunnels, mines or canals; soldiers and travelers exposed to unsanitary conditions of camp life with a large number of men; farmers living in contaminated localities are especially liable.

2. *Anemia* of high grade without a satisfactory cause should direct the attention to an investigation of the blood and stools.

3. *Examination of the blood* in typical cases reveals a condition resembling pernicious anemia. There is a great reduction in the hemoglobin and red corpuscles. Nucleated red corpuscles, however, are few in number and the normoblasts outnumber the megaloblasts. The statement is frequently made that the blood of uncinariasis is a chloranemia, and therein differs essentially from the pernicious type. Such a distinction can usually be made in the milder cases or in the early stages of the disease, but when the blood count falls below 1,000,000 the color index becomes higher and often is above normal. In like manner the volume of the erythrocyte, which is much diminished in the early stages, begins to increase with the progressive oligocythemia and may exceed the normal. This is determined by using the hematocrit in connection with the Thoma Zeiss apparatus, according to the formula: Percentage of erythrocytes by volume (hematocrit) divided by percentage of erythrocytes by count equals percentage volume of the average erythrocyte or volume index. In the present case the last two examinations gave a volume index of 1.17 and 1.22 and a color index of .80 and .88 respectively. We must be prepared, therefore, to find in many of the severe cases a color and volume index essentially the same as occur in pernicious anemia.

In our case macrocytes were present measuring 10 to 12 microns in diameter, but none of the huge cells seen so often in pernicious anemia. Poikilocytosis was less pronounced than usual in primary progressive anemia.

Eosinophilia is the most striking characteristic of the blood when it is present. Most cases of uncinariasis have from 3 to 30 per cent. of eosinophiles. The parasites play two distinct rôles with regard to these cells.

(*a*) A local chemotactic influence which brings eosinophiles in large number to the vicinity of their habitat.

(*b*) A toxic agent secreted by the parasite that is carried to the bone marrow and stimulates the production of eosinophile cells. The evidence of the former process is found in the usual profusion of eosinophile granules in the feces. The latter gives rise to the excess of eosinophile cells in the circulating blood.

Absence of eosinophilia does not at all exclude the possibility of hook-worms.

4. *Examination of the feces* is the only means of making a certain diagnosis. The ova found in a fresh specimen are characteristic, particularly the segmenting forms. *Oxyuris vermicularis* eggs are about the same size, but flattened at the ends; moreover, they are nearly always hatched out before leaving the alimentary canal. Further proof may be obtained by cultivating the larvæ or by expelling the adult worms with anthelmintics.

Charcot-Leyden crystals are almost always present in varying number. Their existence indicates not necessarily uncinariæ, but any form of intestinal parasite. Leichtenstern[31] says they are almost constant with uncinaria and *Anguillula intestinalis*, common with *Ascaris lumbricoides* and *Oxyuris vermicularis* and often present with *Tenia solium*. According to Bucklers[32] the crystals disappear after the worms are expelled, so that the persistence of crystals is proof that some parasites remain in the bowel.

A close relationship seems to exist between eosinophilia and the Charcot-Leyden crystals, as first pointed out by Zappert.[33] In fact, Neusser[34] asserts that the crystals represent a product of the granules. He cites in support of his view that eosinophiles and Charcot-Leyden crystals are both present in leukemia, in the sputum of asthma, in bone marrow, in mucous polypi of the nose and the vesicles of pemphigus. Gerhardt[35] points out the danger of mistaking for these crystals those formed from fatty acids.

Mixed infections are very common. The *Anguillula intestinalis* is not rarely met. Perroncito[36] states that this nematode was often associated with the hook-worm in the St. Gothard epidemic. He believed a graver form of anemia thus resulted than from the single infection, but Bozzolo[37] and Grassi opposed the theory.

In the American series the *Tricocephalus dispar* occurs most often with the uncinaria. Its effect on the patient is probably trivial.

TREATMENT.

The disease is curable if recognized early and treated properly.

The bowels should be cleared the evening before administering the anthelmintic. Thymol in a two-gram dose repeated in two hours and followed by a saline is effective as a rule. Santonin and male fern are not so satisfactory.

Prevention can be best accomplished by:

1. Drainage and drying of swampy lands.

2. Where numbers of men are working in tunnels, ditches or canals, by examination of the feces of workmen and the exclusion of infected individuals.

3. Proper disposal of dejecta in suspected localities by burning or by disinfectants.

4. Enforcement of cleanliness in washing the hands before taking food.

5. A pure water supply.

The case here reported, so far as I know, is the first instance of hook-worm disease originating in Panama. Coming as it does from the Chagres river, which is in the path of the Panama canal, its importance is evident. In the near future thousands of workmen will go from the United States to work on the great canal. Unless precautions are taken, not only will many of these men fall a prey to the disease, but they will bring back and plant the infection in the soil of numberless localities.

PROGNOSIS IN MENTAL DISEASES.*

FRANK PARSONS NORBURY, M.D.

Medical Superintendent Maplewood Sanatorium; Neurologist to Our Savior's Hospital.

JACKSONVILLE, ILL.

In the realm of practical clinical medicine there is no one feature that gives strength to the art and science like that of making a diagnosis. Upon this foundation—diagnosis—must be erected the superstructure of the case, embracing all of the primary essentials, of which it may be said that prognosis, by its approach to the personal element in the case, becomes of very great importance. Prognosis, then, is necessarily founded upon diagnosis. However, there enter into its consideration certain basic or fundamental essentials which make it both an art and a science.

Of the essentials contributing to make prognosis an art we will mention the ability to give estimates based upon experience. Herein are noted the deductions which acuity of observation and abstract reasoning give to the clinician, the quality of the observer which gives color to his art in diagnosis. Again, the cultivation of these faculties or of qualities of mind go to give, or make up that intuitive ability which is the art in its perfection. The science of diagnosis is perhaps more precise and more comprehensive in its observations, but not one whit more practical nor more sure in its forecast. Science in prognosis must found its judgment upon the judgment of diagnosis, which, even when founded upon almost absolute facts, is nevertheless fallible. "The science of prognosis is the science of forecasting; it must look to the art of discrimination, which, in truth, is a personal art; the observer being the artist." We can not draw a line of discrimination between the art and the science of prognosis. All that we can do is to become ourselves observers that we may contribute our mite to the accumulated experience and judgment so that on these may be formulated certain axioms which enter into and are a part of every diagnosis in mental diseases.

"As observations become more accurate as the number of observed cases increases, and as classes are better and better distinguishable, the nearer will the physician be able to approach an accurate prognosis, though the time when any sufficient rules can be applied to individual cases must long be out of our sight and the application of any approximate rules must long be subordinate to the instructive tact of the educated physician himself, who alone can apprehend the sum of the peculiarities which must modify their application to individual instances." (Allbutt.)

In mental diseases the question of heredity is ever of great importance, not so much perhaps as some of the older observers would have us believe, or as important as environment and all that goes with it. Family history should cover both of these questions, viz., the hereditary factor and the environments of the home. It is not timely to here bring into consideration the theory of heredity, even in its most modern conception, but let me enforce what doubtless is the experience of all who have had extended observation of insanity in its varied forms, that aside from the essentially degenerative insanities, environment has more to do in becoming a factor in prognosis than does the much discussed hereditary influences. Family history must, therefore, not only include the search of the family tree, but the soil in which it grows and the ill winds and wafts of fortune and misfortune which play among its branches and affect this one branch in particular.

The etiology of the mental disease is a factor which we all grant is an important one—one, in fact, which alone may give a forecast, and thus proclaim the prognosis even at the first consideration of the case. Again, we are confronted with the hereditary element, which may or may not modify our judgment as to the facts presented. If we will be sure to sift truth from the mass of utterly inconsequential chaff, which is the rule and not the exception in the history of mental cases, then the assigned etiology may be of value. It is impossible to draw any deductions as to prognosis from the tables of etiology published in the average report issued by the state hospitals of this country. Such tables are absolutely worthless as evidence upon which to found even approximate rules of prognosis; they become matters of record through the channels of the average insane inquisition, original hospital receiving records and the lax and superficial observations of the hospital physicians. This statement, of course, does not apply to those institutions in which the science and art of mental diseases is studied and in which the spirit of clinical medicine pervades the work of the staff, from the superintendent down the line to the ward attendants. The study of etiology in such hospitals is worthy of our greatest consideration. We have not sufficiently advanced in mental diseases to formulate definite rules of prognosis as based upon etiology, excepting in essentially organic cases—cases having a definite pathology. In all others we must apply our art and allow for our limitations and shortcomings as individual "artists."

Pathology is contributing its share, and a great share it is, too, toward the solution of problems of prognosis. It is from this field of certainty that we look for the advances that are to open to us many of the mysteries of the mind, and, while we may never cross that seemingly unbridgable, unknowable territory in which abides what we call mind, yet the effort of seeking for it will go on, and possibly deeper recesses may yet be opened to us.

Clinical history is of as much importance as the study of the case in its clinical aspects when first we confront it. We can only formulate deductions of what is to come by a study of what has gone before. We largely judge of the future, in medicine, by the past, and every case wholly upon its merits. The clinical history of every case, therefore, is a prime essential. It must be comprehensive, not superficial, skipping along, hitting the high places here and there, but should embrace all clinical facts, which must be a part of the record. Every case of mental disease is worthy of a record, for when studied closely and properly recorded, facts are accumulated which eventually become axioms upon which prognosis is truly and substantially founded. If every case in our state hospitals had a clinical record (which is worthy of the name of record) uniformly in keeping with all other records, then we could use such knowl-

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Richard Dewey and H. A. Tomlinson.

edge in formulating clinical deductions, then the science and art of mental diseases could better be studied and their effects for good or evil better known. Especially is this true of the study of diseases of metabolism—a class of diseases which modern chemical pathology is showing has a very important bearing upon mental diseases. In fact, we may say that, as this department of pathology develops, many of the problems which confront the chemist and the neurologist will be shown to be problems of clinical medicine.

The work of Christian Herter of New York is doing much towards the establishment of a more definite prognosis in mental disease, and opening the way for great advances in the treatment of these conditions. Herter's work shows how necessary it is for the successful chemist—the successful neurologist—to first be a successful physician, a broadly trained observer, a widely experienced practitioner, so that the whole scope of internal medicine may first be viewed before measuring the limitations or encompassing the field within the narrow confines of the specialty of nervous and mental diseases. When we become broad enough in our art and science prognosis will then be more comprehensive. Prognosis must, of course, always depend upon the observer; his art and science will say whether or not the prognosis is comprehensive. However, we endeavor in formulating a prognosis to determine the prospects in the case under consideration. This is summarized from a diagnostic study—a differential study of the points in diagnosis, and last, the condition of the patient.

If from the first study a diagnosis is determined then the prognosis will be based upon the nature of the case and our own personal deductions based upon our experience in similar cases, our knowledge based upon the experience of others and the literature of to-day. The rules are not absolute, but vary with the elasticity of our own experience and knowledge. The patient's future or forecast is determined largely on the result of our study of his attack. We have diagnosed the form and class of cases to which the case belongs, and then within the limitations of our experience and knowledge we are able to give at least a prospect—a judgment—the reliability of which varies with judgment of the observer.

The patient's future is of importance to himself and his friends and we can do no better act within our art than to give a prognosis in mental disease. We can be of no greater use to the friends and those depending upon him than that embraced in giving a prognosis. It must be remembered that a prognosis thus given must be founded on a summary of the whole art and science of prognosis and when thus given with the sincerity of an honest and conscientious clinician, then a duty well done has been discharged. The patient's future has an important bearing upon his descendants, but only in so far as the question of heredity enters, and also the question of environment which has contributed toward the evolution of mental disease. The mere abstract question of the effect upon the children born after mental disease or during mental disease is one to be determined in each individual case; a question requiring careful judicious consideration, and not to be lightly or flippantly disregarded.

In my own experience the question of prognosis is one which appeals to the whole of one's manhood, touches our heart strings, and gives earnestness of endeavor in treatment. It is a problem which concerns more than the individual and, in fact, more individuals in mental disease than in any other class of cases in internal medicine; hence we must cultivate broad and comprehensive ideas in our observation and study, grasp every opportunity to increase our knowledge and experience that we may be one of the many observers who are adding to accumulating knowledge of mental diseases upon which the art and science of prognosis must rest.

In conclusion, I would say that:

1. Prognosis is both an art and a science.

2. Prognosis should be founded upon the following: *a,* family history; *b,* etiology; *c,* pathology; *d,* clinical history; *e,* complexly related physical diseases.

3. Prognosis should be comprehensive and attempt to consider: *a,* the prospects in the present attack; *b,* its effect upon the patient's future; *c,* its effect upon his descendants.

Clinical Report.

A CASE OF URETERO-TRIGONO-INTESTINAL ANASTOMOSIS FOR THE RELIEF OF EXSTROPHY OF THE BLADDER.*

JULIUS H. JACOBSON, M.D.
SURGEON TO LUCAS COUNTY INFIRMARY HOSPITAL.
TOLEDO, OHIO.

The patient is a male, aged 29, who entered the Lucas County Infirmary Hospital April 2, 1902. The father died of Bright's disease; the mother of so-called dropsy; brothers and sisters all living; no tuberculosis or cancer in the family.

The patient relates that since birth he has had no control over his urine; it has always dribbled away, but he did not know what it was. He was operated on, when still a child, in Griefswald, Germany, but can not give the exact nature of the operation. He has always been obliged to wear some sort of receptacle to hold the urine, otherwise he has enjoyed the best of health. About one year previous to his entrance to the hospital, he underwent several operations for the relief of his condition. These operations consisted in the endeavor, by means of plastic operations, to cover the defect in the bladder, but they were not successful. At the same time he also underwent an operation for the relief of a large left inguinal hernia, which was thereby cured. He states that previous to these operations his genitals consisted of a rudimentary penis which was double, and that the urine flowed from one side of the organ. The rudimentary penis was removed during the plastic operations.

Examination of the patient, at time of entrance, revealed a well-nourished, tall, muscular individual presenting no emaciation; heart, lungs, liver and spleen were apparently normal. Above the symphysis pubis is an area of deep red tissue looking like granulation tissue and covered by a purulent secretion, which on close inspection proves to be a part of the bladder; from the lower part of same the urine can be seen to spurt at intervals of thirty to sixty seconds; both ureteral orifices can be seen and ureteral catheters passed into them. The abdominal wall, as well as the anterior wall of the bladder, is absent, which permits the posterior wall to prolapse forward.

The diagnosis of exstrophy of the bladder was easily made. Catheterization of the ureters, and examination of the separate urines gave the following: Left kidney—urine runs very freely through the catheter and is of a clear amber color, acid in reaction, highly albuminous; on microscopic examination, epithelial cells, leucocytes, urates, but no casts, are found. Right kidney—urine is of a dirty grayish color, flocculent and opaque, containing albumin, but not so much as is present in the other kidney; on microscopic examination, there are found great quantities of pus, red blood corpuscles and epithelial cells, but no casts. The urine examination reveals mainly the following facts: Both kidneys are the seat of chronic inflammation; the

* Presented before the Lucas County Medical Society, Oct. 3, 1902.

right one more so than the left, which is the result of ascending infection.

OPERATION.

A uretero-trigono-intestinal anastomosis, modified after Maydl, was made on April 19, 1902, Drs. Brewer and Steinfeld assisting. A mixture of chloroform and ether was the anesthetic used. The patient was prepared in the usual manner, while special care was given to the sterilization and preparation of the exstrophied portion of the bladder, which was the infected area to be feared. A ureteral catheter was passed into each ureter; the incision made immediately above the bladder about four inches in length and the peritoneal cavity opened; the patient raised to the Trendelenburg position. The intestines were held back by sponges. The incision was carried downward through the center of the bladder (between the ureters), dividing it in two. The ureters could be plainly seen, running outward, backward and upward; with the catheters in them they were surprisingly large and easy to manipulate, which greatly facilitated the work. Each ureter was dissected free by cutting it away from the bladder, leaving a circle of bladder tissue about one-half inch around the vesico-ureteral

Six months after operation.

openings, thereby leaving the natural ureteral openings into the bladder unmolested. The peritoneum on the right side was incised and reflected along the course of the ureter, permitting the ureter to be lifted from its bed. The peritoneum was further stripped from the posterior wall of the pelvis around to the rectum. An opening into the right lateral side of the rectum was next made, at about the level of the sacral promontory, into which the ureter with bladder-wall attached was sutured; first mucosa of bladder to mucosa of rectum by a continuous silk suture (black iron-dyed silk), then serosa of bladder to serosa of rectum with a like continuous suture. A few interrupted sutures were also applied to make the anastomosis more secure. The reflected peritoneum was finally sutured back into place (by a continuous catgut suture) making the entire anastomosis covered by peritoneum and placed extraperitoneally. About three and one-half inches of the lower part of the ureter was placed in a new position. The same procedure as described for the right side was made on the left side; the anastomosis on the left side being made opposite to the one on the right, a trifle lower. The peritoneal cavity was thoroughly irrigated with salt solution, sponges removed and patient lowered to the flat position. All of the remaining portions of the bladder walls were extirpated, hemorrhage being controlled by ligatures and cautery.

The incision was closed by interrupted silkworm-gut sutures supplemented by layer suturing of catgut. In the lower angle of the incision, where tension was great, a few tension sutures were applied. A large drainage tube was left in the lower angle of the wound, and the whole abdomen supported by broad adhesive plaster strips.

After the operation the patient suffered severely from shock, but, under stimulants and salt infusions, recovered. Immediately after the operation, the urine seemed to irritate the rectum, the desire to urinate being constant, which gradually disappeared as the rectum became more tolerant, until a tolerance of three to four hours was obtained. The abdominal wound became infected as was anticipated, suppuration was profuse which ceased after a time, allowing the wound to heal gradually, until at present it is practically closed.

The patient's condition at present is as follows : He is able to get around with no inconvenience; does considerable work about the hospital, wearing an abdominal bandage; voids urine through the rectum every three hours and states that he can hold it as long as six hours, if he wishes to do so. The bowels move regularly, and the urine is voided independent of bowel evacuations. He states that sometimes during the night the urine is passed unconsciously, during sleep. About three weeks ago he relates having passed a stone from the rectum, the nature of which was not determined, but may have been a calculus formation or lime deposit about the opening of the ureters into the rectum. The abdominal incision has united and is practically healed; in the lower angle is a small area of granulation tissue where the bladder was extirpated; this is dressed daily and is rapidly closing. In the upper angle of the incision a slight hernia has developed, which is especially noticeable when the patient is in the upright position.

Demolition of "Crazy Tower" at Vienna.—The great city hospital at Vienna is to be rebuilt and the famous round tower in which the insane were confined will soon be demolished. It was built about 1780, and usually contained 270 inmates crowded into small cells, four in a cell. There are no windows and merely narrow slits in the thick wall for light and air, with no means of heating the rooms. Of late years it has been used as a store room.

The Teaching of Common Diseases.—It has been said, and with some reason, that an average medical student, on graduation, is far better prepared to treat diseases and conditions he is never or rarely likely to see than those of common occurrence. He has probably seen much of major surgery, and is well informed regarding typhoid fever and diseases of the blood, but when he is brought face to face with a cold or a backache or any of the thousand and one minor ills of life, he is far less a master of the situation. It would be a poor policy to neglect the rarer affections for the sake of the commonplace, but it is almost equally unfortunate and far more unpractical to ignore the latter in the hope their knowledge of them may somehow come in later life. The fact apparently is that the instruction given is apt to concern itself chiefly with disease in its unusual manifestations. Interesting cases predominate. We rarely hear of a clinical exercise before a class devoted to the everyday variations from health. A course in common diseases remains to be offered, and our students are suffering in consequence. A remedy is perhaps difficult to find in the wards of a large hospital, where the patients are admitted for various reasons, but certainly not because they are commonplace. The solution lies in the more intelligent and systematic use of out-patient departments, to which each day great numbers come afflicted with the most trivial ailments. If the students could actually study these patients, under the direction of authoritative teachers, they would gain a knowledge which the ordinary clinical lecture is not likely to give. How this may be done is a matter of detail, but for out-patient departments to be used chiefly as opportunities for physical diagnosis and not for the detailed study of disease as such, is a misfortune which our improved organization should do all in its power to remedy. —*Boston Med. and Surg. UNCINARIASIS (ANKYLOSTOMIASIS) IN THE SOUTHERN STATES.

A little over a year ago we stated[1] from facts then known that ankylostomiasis or uncinariasis was apparently a rare affection in the United States. Later data have modified this view, numerous cases have been observed, one of which very completely reported is published in this issue. During the past few weeks, moreover, some very important observations have been made in the Carolinas and Georgia, which are not only of great scientific interest, but which also will probably be of great value in improving the economic and physical conditions of the poorer population of some of the southern states. These observations have led to the discovery that "hook-worm" disease is extremely prevalent among the poorer classes of the southern whites.

Ankylostomiasis, or, more properly speaking, uncinariasis, has for generations prevailed more or less extensively in various parts of Europe and in Egypt. It is known under various names, such as tunnel disease, tunnel anemia, miners' anemia, brickmakers' anemia, Egyptian chlorosis, tropical chlorosis and hook-worm disease. It occurs most frequently in persons whose occupations necessarily bring them in contact with fresh or dried earth. It was the disease that proved so fatal to the workmen engaged in the construction of the St. Gothard tunnel. It is due to infection of the intestinal tract, particularly the duodenum and jejunum, with a small nematode parasite, the *Uncinaria duodenale,* the male measuring from 6 to 10 mm. long, and the female from 10 to 18 mm. The parasite produces anemia, not only by sucking blood, but also by causing an injury to the intestinal wall where it has attached itself, from which oozing of blood continues after it has let go. There is a possibility also that it produces a toxic substance which has a hemolytic action on the red blood cells. The eggs develop only after leaving the intestinal tract, so that for every adult hook-worm present in the intestine a separate larva must enter the body. Infection is believed to occur usually by the individual conveying the larvæ to his mouth on infected hands. Loos, in 1901, published the results of experiments which led him to believe that infection occurred by larvæ entering through the skin. During the present year, Bentley advanced the view that "ground-itch" or "pani-ghao," a cutaneous disease, is due to the entrance, subcutaneously, of hook-worm larvæ.

Previous to 1902 not more than twenty-five observations had been reported in the United States. These infections were all believed to be due to the European species. In May, 1902, Dr. Stiles of the United States Bureau of Animal Industry, Washington, reported[2] that he had discovered a new species of uncinaria, to which he gave the name *Uncinaria americana,* in the feces forwarded him from a case in Galveston, Texas. This parasite differs from the old-world species in two main features: the eggs are considerably larger and the two ventral, recurved hook-like teeth of the adult are replaced by a pair of semilunar plates in the American species. Stiles[3] has recently described this parasite more fully in a bulletin issued by the Department of Agriculture. Since then observations have been accumulating to show that uncinariasis is very common in some of the southern states. All the infections appear to be due to the new American species. H. F. Harris of Atlanta reported his first case in July, 1902, and since then he has observed thirteen cases, eleven in Georgia and one each in Alabama and Florida. He believes that the disease is a much more frequent cause of severe anemia in the south than is malaria, and is of the opinion that investigation will prove that it is the most prevalent of all the severe diseases in the southern states. Guiteras has reported cases from Florida and Cuba, and the disease is known to prevail in Porto Rico.

Recently, Stiles has spent considerable time in the Carolinas, Georgia and Florida investigating the prevalence of uncinariasis. He made a preliminary report[4] of his studies at a meeting of the Sanitary Conference of American Republics, held in Washington, December 2 to 4. He finds that the disease is extremely prevalent among the poor whites of the sand and pine-woods districts of the south. He believes that its prevalence in succeeding generations has resulted in the inferior physical development and lowered mental caliber of these people, and that it is the cause of the proverbial laziness of the southern "cracker." Men and women of 20 to 23 years of age resemble in appearance children of from 14 to 16. The disease is believed to prevail also in the "dirt-eaters." In this remarkable malady there is a vicious circle, the uncinariasis probably being in part responsible for the depraved appetite and the depraved appetite keeping up the infection. Owing to the marked secondary anemia produced, uncinariasis closely resembles chronic malaria, for which it has long been mistaken. The disease is readily recognized by finding in the stools the characteristic segmenting ova, from which the embryos can be easily cul-

tivated. Fortunately, it is usually amenable to treatment. Thymol in 30-grain doses at 8 and 10 a. m., followed by a purgative at noon, nearly always clears the intestinal tract of the adult worms.

It can readily be seen what a far-reaching effect this most important discovery will probably have in improving the physical and mental status of the poorer classes, both white and colored, of the south. It is most sincerely to be regretted that the daily press in certain parts of the country has, as is too often the case, done much to throw discredit on scientific investigations by announcing to the public in a most sensational manner that "The Germ of Laziness Has Been Discovered."

THE VIRUS OF SMALLPOX.

The minute bodies discovered in the vaccine lymph of calves by Van der Loeff still continues to puzzle investigators. Reasons for this are the repeated failures to find, even by improved methods of bacteriologic research, any specific micro-organism as a cause for variola and the difficulty in accounting for the vaccine bodies except as parasites. Foremost among those works maintaining their intrinsic somatic origin is that of Hückel ascribing them to a specific degeneration of the epithelial cells; prominent among the supporters of their parasitic nature is Guarnieri, who concluded, from a study of their morphology as they occur in the vesicles produced by vaccinating rabbits' corneas, that the vaccine bodies are protozoa.

Soon after the work of Guarnieri, L. Pfeiffer found them in the blood of both variolous and vaccinated people as free, swimming, nucleated bodies, one-fourth the size of a red corpuscle. These observations were soon confirmed by Reed in this country, who found similar bodies in the blood of vaccinated monkeys and calves. Although he also found them in the blood of a monkey and a child, both of whom were unvaccinated, he stated that the vaccine bodies are greatly increased in the blood during the height of vaccinia, whereas before and after such periods they are rarely seen.

Experiments directed to their artificial cultivation have been made repeatedly; lymph containing them has been transferred to both fluid and solid media, and at later periods animals have been vaccinated from the media. The objection made to such experiments are that successful vaccination was due to the employment of diluted virus rather than freshly grown vaccine bodies.

Other observations similar to those noted above and evidence from various sources of the identity of vaccinia and variola have served to augment the importance of the vaccine bodies—occasionally referred to as Guarnieria—as possible causative agents of both conditions. The work of Wasielewsky[1] in no small degree increased the growing interest in this problem. He produced corneal vesicles by vaccination in 46 rabbits by transferring the exuded lymph from one animal to another successively; demonstrated the constant presence of vaccine bodies in the lymph and ascertained that when filtered lymph was employed the bodies were absent and no vesicles formed. These observations apparently make the development of the eruption of vaccination contingent on the presence of the bodies in question, yet it is not unlikely that the real *causa causans* has escaped discovery, that in the experiments of Wasielewsky it, too, failed to pass the filter and that the vaccine bodies represent the consequences in part of its action on the tissues. Ishigami[2] has recently announced the artificial cultivation of these alleged protozoa. In order to procure material free from bacterial taint, he made intravenous injections of vaccine lymph in calves. From the vesicles that appeared after a few days on various mucous surfaces and the inner aspects of the thighs and ears, he obtained lymph uncontaminated with bacteria; later he secured the same result by adding small quantities of carbolic acid to lymph. The medium on which the vaccine bodies were grown consisted in large part of epithelium from unvaccinated calves. The evolution of the parasite in cultures made from the crusts of variolous or from human or bovine lymph resembled the series of changes these bodies undergo in the tissues. Vaccination with subcultures was successful until the fourth transplantation; the animals vaccinated with such cultures remained refractory to further vaccination and the vaccine lymph collected from them produced typical vesicles in others.

The production of vaccinia with subcultures removes the objections of those who would attribute any success from cultures to the virus originally sown on the medium. On the other hand, it may be that vaccination from cultures of the second and third transplantations was due to the growth of some ultra-microscopic organism, as yet undetected, instead of vaccine bodies. The contribution of Ishigami is nevertheless an important one; its results should be confirmed by others and the nature of the vaccine bodies determined.

On reviewing the accounts of the vaccine bodies and the opposing views as to their interpretation, a marked similarity with the history of the so-called protozoa of cancer is evident. In cancer and in the lesions produced by the virus of smallpox, the structures described as parasites appear in the epithelial cells and there many details of morphology and tinctorial reactions common to both. In both cases there is a small body of enthusiastic supporters of the protozoan character of the suspected parasites.

OCCASIONAL DIAGNOSTIC DIFFICULTIES IN SURGERY.

Some weeks ago[3] we commented on the unfortunate outcome of an operation which illustrated some of the unavoidable diagnostic errors in surgery. Since then

3. THE JOURNAL A. M. A., Oct. 25, 1902.

the case has been reported in full,[2] showing in much stronger light the difficulties under which the operator must labor and the misleading character of the symptoms in certain cases.

In this case the patient had on a former occasion accidentally swallowed his false teeth, and was positive that he had done the same again. It seemed almost certain that he did swallow them, but unconsciously relieved himself in his efforts, and then continued to struggle with his hyoid, the external cornua of which he could touch, believing it to be the plate he had swallowed, thus severely lacerating his throat. The obstruction became complete, only rectal feeding was permissible, and the inflammation extended to the air passages, necessitating an emergency tracheotomy. The diagnosis was misled by the skiagram in which a calcification of the aorta caused a shadow resembling the plate; this and the seriousness of the symptoms, all out of relation to the local operative traumatism, rendered operation imperative. Only after it had proved the absence of the foreign body did the family abandon their opinion and renewed search reveal the missing teeth. Thirteen physicians were familiar with the case, were present at the operation, and none of them questioned the diagnosis. The whole case seems to have been managed with all the cautions that surgical knowledge could suggest, and the fatal outcome, we judge from the report, was probably not hastened or influenced by the operation.

Dr. Crile's paper, referred to above, contains a useful study of the literature of approximately similar cases. A strikingly similar one is that reported by Lund,[3] in which the presence of a supposedly swallowed set of teeth was diagnosed by a lecturer at the Royal College of Surgeons, the cornua of the hyoid being actually felt while the autopsy showed the absence of the plate. The deduction drawn is that neither the sound nor the *x*-rays are infallible aids to diagnosis, and the reported cases show that distinguished surgeons as well as patients have mistaken the hyoid for a tooth plate impacted in the esophagus. Considering the greatly heightened mortality rate of the non-operative treatment of such cases, the urgency of the symptoms in the case reported, entirely apart from the question of the actual presence of the plate and the error of the diagnosis, it does not seem to us that there was any defect of good surgical judgment in the course adopted.

OPERATIVE TREATMENT OF EPILEPSY.

Idiopathic epilepsy was long considered a disease belonging to the field of internal medicine, and is still so considered by many. From time to time, however, enterprising surgeons report results of series of cases subjected to operative treatment with more or less success. In the intervals between such reports some lose sight of the fact that such cases have been treated surgically, and consider the operative treatment of epilepsy something new. Most of the earlier operations found their justification on the basis of animal experimentation. Physiologists have demonstrated that sudden anemia of the brain, such as is produced by ligation of both the carotid arteries and the vertebral arteries simultaneously, will produce an epileptic attack.

On the other hand, there is some experimental basis for the supposition that brain hyperemia produces epilepsy, and a number of surgeons have practiced ligation of the vertebral arteries with the idea of curing epilepsy by preventing brain hyperemia. Among the later operations is resection of the cervical sympathetic ganglion, and since the introduction of this operation the benefit of ligation of the vertebral artery has been attributed to the accidental division of the sympathetic nerve, or nerves, during the operation of ligation. The resection of the cervical sympathetic ganglions prevents sudden occurrence of anemia of the brain by paralyzing the vasomotor constrictor nerves, the nerves which produce contraction of the smaller vessels of the brain. If epileptic attacks have their origin in brain anemia, this operation has at least theoretical justification. Sporadic cases had been reported from time to time, but in 1896 Jonnesco of Bucharest brought the subject prominently before the profession at the Surgical Congress at Paris and reported 97 operations of this kind which he had collected from the literature or personally performed. Jonnesco now maintains that it is necessary to excise all three of the cervical sympathetic ganglions on both sides of the neck. The immediate effect of the operation is to produce hyperemia of the face and conjunctiva, contraction of the pupil and ptosis. The symptoms are usually transitory and no permanent trophic disturbances have been reported. The operation has not been attended by death in any case and the percentage of recoveries in over 200 cases is placed at about 6 per cent. Although this is not brilliant, it is more satisfactory than the treatment of epilepsy by bromids or other medical means, which scarcely yield 2 per cent. of permanent cures. The operation is relatively a new one and its indications are not yet well understood. Possibly, when cases can be better selected, particularly if earlier and less severe cases are taken, the results may be more satisfactory.

Craniectomy has been long recognized as a most satisfactory treatment for all cases of traumatic epilepsy, but few have attributed any value to the operation in idiopathic epilepsy. Kocher has been one of the chief advocates of the operation in idiopathic cases, and reports patients who have been without attacks for over three years. The operation is based on the theory that epileptic attacks are caused by increased intracranial tension with brain hyperemia, and by removing a portion of the skull a safety valve is formed which prevents recurrence of abnormally high intracranial pres-

2. Cleveland Medical Journal, December.
3. Brit. Med. Jour., 1885, I, 1142.

sure. Many investigators, for example Von Bergmann, Dejerine, Bier, Braun and others, hold that the theories with regard to circulatory disturbances are without sufficient foundation and consider operation absolutely unjustifiable.

Our information at present is fragmentary and based on entirely too much theorizing. Possibly some cases may be due to brain anemia, while other cases are the result of brain hyperemia. Further experimental studies along these lines are needed and, it would seem, might yield valuable results.

AN EDITOR'S VALEDICTORY.

Dr. Malcolm Morris publishes his valedictory as editor of the *Practitioner* in the December issue of that journal. We do not know who is the "younger and swifter runner" to whom he resigns his place in medical journalism, but he will have to be a worthy one to fill the place held by Anstie, Brunton and Morris. The *Practitioner* has been one of the brightest as well as one of the most solid and scientific of our British exchanges, and it is to be hoped that it will lose none of its good qualities by its change of editors.

A COMMEMORATION OF LISTER'S WORK.

The issue of the *British Medical Journal* of December 13 is a special Lister number, commemorating the completion of fifty years of medical practice of Lord Lister. The editor has made it a sort of Festschrift, made up of contributions by various eminent followers of Lister's teachings in different countries, Von Bergmann and Mikulicz-Radeski in Germany, Lucas-Championniere of France, Durante of Italy, Bloch of Denmark, together with those of several British surgeons, Ogston, March and Berry Hart. The history of antiseptic surgery as it developed under the initiative of Lister is given by Annandale, Sir Hector Cameron, John Chiene and Watson Cheyne. It is to be regretted that there are no American contributors, for what Lister has done for surgery is nowhere more appreciated than in this country, and nowhere, we believe, are the results more apparent. The editor of the *British Medical Journal* informs us that it was the original plan to have such included, but for some reason or other those who were depended on did not supply them. As it is the number is a pleasant tribute to one of the greatest advancers of surgical technic and success.

JOINT CHANGES IN TABES.

The pathogenesis of the arthropathias is still in doubt. The rôle of trauma, analgesia, neglected rheumatic effusions, rarefaction, epiphyseal separation and bone atrophy as an end result of syphilis are still denied as causative factors by many who look on the condition as induced in some manner by the peculiar and inherent nature of the disease itself. Since the macroscopic, chemic and histologic investigations of Regnard, Féré and Blanchard on the bone changes in tabetics, no one has seriously doubted the importance of these tissue alterations as factors in the arthropathias of this disease. However, the extensive study of Kienböck six years ago on tabetics by means of radiography gave no abnormal picture, neither in the arthropathic joints nor in any of the free articulations of such patients. While this investigation was a surprise to those who believed in the theory of rarefaction and bone atrophy, it failed of conviction in the presence of the more accurate microscopic and chemic studies on tabetic bone which had been previously made. In a review of the contending theories Donath[1] reports two very instructive cases of arthropathia in tabetics. In one, a typical Charcot knee was accompanied by a corresponding enlargement in all the calf muscles. The changes in the soft parts were identical in character and originated from an extension of the effusion and infiltration from the adjacent tabetic joint. The same case showed arthropathia of the elbow joint in which the triceps tendon became calcified apparently on account of immobilization. This fact suggests a practical rule: Do not permit the use of a bandage compress for too long a period as a corrective without active or passive movement of the joint. In the second case the second joint of the index finger, an unusual seat, was involved, together with its tendon (contracture). Both cases were undoubtedly luetic-tabetics and the joint changes were typical of the affection. Radiographic study showed the light shades very well, the existence of which as signs of rarefaction are denied by Kienböck. Donath emphasizes the fact that during the inactivity of the bone atrophy, radiography fails to give a typical picture. In point of fact it does not show itself in an active stage except in those cases which are ultimately fractured; hence the discrepancy in the different radiographic investigations of tabetics. Indeed, they often fail to show positive signs of epiphyseal fracture even with good technic, if rarefaction and decalcification are not great, and if the parts are buried somewhat deeply by soft parts, such as that of the knee and hip. The decalcification of bone which constitutes the predisposition is a nutritional disorder, probably the result of syphilitic endarteritis which hinders a proper blood supply. The author finally gives us the latest summary of the pathogenesis of the condition: A bony change with analgesia, in which spontaneous articular fracture occurs or is induced by slight trauma; such injury because of its painlessness and apparent trivial nature is often overlooked.

Medical News.

ILLINOIS.

For Mattoon Hospital.—Dr. David M. McFall has donated 360 acres of Coles County land to the proposed public hospital at Mattoon.

Anonymous Donor.—A Christmas gift of $1,000 from an unknown donor, to be applied on the outstanding indebtedness of $11,000, has been received by the Evanston Hospital.

Addition to Swedish Hospital.—The new section of the Swedish Hospital, Bowmanville, erected at a cost of $30,000, will increase the capacity of the institution to the extent of 75 patients.

Chairmanship of a County Board.—Dr. William R. Harper has accepted the position tendered him by the president of the county board and will serve as chairman of the advisory board of the Cook County Hospital.

1. "Contribution to Tabetic Arthropathias," by Dr. Julius Donath, Wiener Klinische Rundschau, vol. xvi. No. 43, Oct. 26, 1902.

The Parke Banquet.—The McLean County Medical Society gave a banquet, December 15, in honor of Dr. Charles R. Parke, Bloomington, who after fifty-five years' practice is about to leave Illinois and settle in Kentucky. Dr. Lee Smith acted as toastmaster, and Drs. William Hill, Franklin C. Vanderwort, James B. Taylor and Daniel M. Foster responded to toasts.

Chicago.

No Hospitals on Boulevards.—An ordinance has been passed prohibiting hospitals and infirmaries on boulevards under the control of the west park board.

Physician Reprimanded.—An Englewood physician, who is alleged to have instructed a smallpox patient to go to the health department by way of the street cars, thereby running the risk of exposing others to the disease, was reprimanded by the department for so doing.

Personal.—Dr. William B. Wherry, assistant in the department of pathology and bacteriology at the University of Chicago, who has been appointed pathologist to the Government Laboratory in Manila, Philippine Islands, left for Manila, January 1.——Dr. Warren H. Hunter has been reappointed county physician.——Dr. Otto W. Lewke has been appointed coroner's physician, vice Dr. George Leininger, resigned.

Preponderance of Female Deaths.—The abnormal preponderance of deaths among females, 305, to 293 males, in the week ended December 27, is accounted for by the health department by "the defective street car service, with its frequent breakdowns at a season of the year when thousands of women, at a high pitch of nervous tension over the holiday shopping, have been kept waiting for hours exposed to the inclemencies of the weather."

The Week's Deaths.—The mortality-rate for the week ended December 27 was 17.12 per 1,000 per annum, which compares favorably with 17.98, that of the previous week, but is much higher than that of the corresponding week of last year, which was only 15.03 per 1,000. The preponderant causes of death were pneumonia, 91; heart disease and tuberculosis, each 50; typhoid fever, 39; intestinal diseases, 36; nephritis, 35, and violence, 19.

For Sick and Crippled Children.—At a meeting of physicians and laymen held under the auspices of the Woman's Club, preliminary steps were taken to incorporate a society to provide for adequate establishments for the care of children suffering from contagious diseases, to encourage scientific research as to the best methods for preventing epidemics of these forms of sickness, and to provide for the care of crippled children. Dr. Frank Billings presided, and addresses were made by Drs. John M. Dodson, W. S. Christopher, Arthur R. Reynolds, Ludvig Hektoen, John B. Murphy, A. J. Ochsner and others.

Lemon Juice a Germicide.—The publicity given in the daily press to a cablegram alleging that lemon juice was a powerful germicide, with especial reference to the typhoid bacillus, has led the health department to experiment, with the following preliminary results:

> The following experiment was made in the laboratory to test the value of lemon juice in destroying the typhoid bacilli: One hundred and twenty c.c. of bouillon was inoculated with the *Bacillus typhosis*. The flask was placed in the incubator at 90 degrees for 12 hours. At the end of this period 4 c.c. of lemon juice was added. At the end of four hours plates were inoculated from this flask. The plates at the end of 24 hours showed no growth.

Further investigations will be made, and the department says lemon juice may be recommended as a prophylactic if results prove its value.

KANSAS.

Colleges Not Merged.—The negotiations for the absorption of the Kansas Medical College, Topeka, by Washburn College have fallen through, and an attempt is now being made to affiliate with the state university at Lawrence.

Personal.—Dr. Samuel W. Willison, Lawrence, is now professor of paleontology in the University of Chicago.——Dr. Charles Loomis has moved from Lawrence to Eudora and Dr. John Cahill from Lawrence to Birmingham, Ala.

War Against Unlicensed Practitioners.—The state board of medical examination and registration is waging war against unregistered physicians. J. S. Hamilton, Independence, has been convicted in the Montgomery County District Court, and C. H. J. Jordan, Kansas City, has been prosecuted in the Common Pleas Court of Wyandotte County for illegal practice.

MARYLAND.

Personal.—Dr. George Johnson has left Frederick and will reside hereafter in Florida.

Hospital for Cecil County.—A public meeting looking to the establishment of a county hospital at Elkton was held at that place, December 17. Dr. Charles M. Ellis, Dr. George S. Dare, Dr. Howard Bratton and Dr. John H. Jamar are among the incorporators.

Baltimore.

Prize for Health Department.—The commissioner of health has received from Paris a handsome bronze medal, won by the Baltimore health department for having the best exhibition of health and mortality records shown at the Paris Exhibition in 1900.

Increased Death Rate.—The health department reported a larger death rate last week than for many weeks past. This result is attributed to the epidemic of measles now prevailing and to the large number of cases of pneumonia consequent partly on the measles and partly on the lack of fuel supply. There were 211 deaths—a rate per 1000 of 20.20 per annum. Among the causes of death were pneumonia 40, tuberculosis 23, Bright's disease 18, measles 5. There were 216 new cases of measles reported, 34 of diphtheria and 9 of typhoid fever.

Personal.—Dr. William Osler will read a paper at the one hundredth anniversary of the New Haven Medical Society, January 5.——Dr. Edward N. Brush gave a reception at the Sheppard and Enoch Pratt Hospital, December 15.——Dr. F. O. Rodgers, who has been one of the resident house physicians at St. Joseph's Hospital for the last two years, has left for Concord, N. C. Before his departure he was given a dinner by the house staff.——The venerable Dr. John Morris is very ill at the City Hospital, and no hope is entertained of his recovery.

NEW YORK.

New York City.

Personal.—Dr. Thomas H. Manley was tendered a reception by the profession of Hartford, Conn., December 22.

Christmas in the Hospitals.—Bellevue and the other city hospitals had a red-letter day on Christmas, owing to the liberality, it is said, of Mrs. Cornelius Vanderbilt, who, desiring to show her gratitude for the recovery of her husband from typhoid fever, sent a check for $500, to provide good things for the patients on Christmas.

Bronx Vital Statistics.—The annual report for this borough shows there were 4756 deaths, an annual rate of 29.08 per 1,000, but if the 1,404 deaths of non-residents, for the most part patients in institutions, were excluded, the death rate would be reduced to 13.72, an exceptionally low rate. There were 4,938 births reported, but many births undoubtedly were not reported.

Dr. Lorenz Departs.—Dr. Adolf Lorenz has followed the schedule laid down for him for the past week. Everywhere he has received an ovation. December 26 he dined with the orthopedic section of the New York Academy of Medicine, and following this a reception was given him at the Academy. On Sunday he operated at the New York State Hospital for Crippled Children, Tarrytown. After doing a few more private operations, and being entertained at dinner by Austro-Hungarians, Dr. Lorenz embarked on the *Celtic* for Liverpool December 31.

PENNSYLVANIA.

The Free Hospital for Poor Consumptives, up to December 13, had received contributions amounting to $8,500.

Child Insurance.—John and Emma Williams have recently, by a coroner's jury, been committed to prison to await investigation by the grand jury, charged with the fatal poisoning of their two children. The securing of insurance on the lives of the children is the motive ascribed. This and other suspicious cases of a like character have led to a movement on the part of Insurance Commissioner Durham, and also of reputable insurance companies, to stop the practice of insuring young children. A bill to be presented to the legislature will contain a clause placing the minimum age limit probably at 6 years, and also limiting the amount of insurance that may be taken on a child.

Philadelphia.

Campaign of Vaccination.—Fear is not entertained of an epidemic of smallpox such as occurred a year ago, but, as a precaution, in its determination to avert such an epidemic, the Department of Public Safety will again conduct a campaign of vaccination. Police lieutenants have been ordered to have the patrolmen make a house-to-house canvass, taking a census of persons who have not been successfully vaccinated within the last five years. When the canvass is complete, city vaccine

physicians will call on and vaccinate those who will submit to it.

High Death Rate.—The death rate was high for the week ended December 20, there being 535 deaths, 76 more than in the preceding week, and 103 more than in the corresponding week of 1901. Fifteen new cases of smallpox were reported. Dr. Benjamin Lee, secretary of the State Board of Health, announces that Philadelphia is more free from the contagion of smallpox than any other portion of Pennsylvania. He states that the disease has been worse in Pennsylvania for the past four months than for a corresponding period a year ago; that it is spreading throughout the state, and that because of the lack of funds to fight its spread, the situation is a serious one. For the year ended December 1 there were 5,867 cases of smallpox and 446 deaths within the state. Within November 375 cases, with 66 deaths, occurred, while in the same month of 1901 249 cases and 40 deaths occurred. Comparison of other months shows a like increase.

Personal.—Dr. Thomas L. Coley has been appointed visiting physician to the Methodist Hospital, vice Dr. J. P. Crozer Griffith, resigned.——Dr. Alfred Hand, Jr., has been appointed visiting physician to the Children's Hospital in place of Dr. Frederick A. Packard, deceased.——On December 20, before the American Academy of Political and Social Science, General Leonard A. Wood, U. S. Army, reviewed the military administration of Cuba, dwelling especially on the present condition of the charities, the sanitary provisions, and the public works and finances of the island.——On December 18 Dr. Matthew D. Mann, Buffalo, delivered an address before the Charles B. Penrose Gynecological Society, and was afterward the guest of honor at a reception given by Dr. John G. Clark at the University Club.—On December 17 Dr. Norval H. Pierce, Chicago, read a paper before the Section of Laryngology and Otology of the College of Physicians, and was afterward entertained by Dr. D. Braden Kyle at a smoker and reception at the University Club.

GENERAL.

Cholera Continues in Manila.—Thirty cases a day were being reported a month ago. The death rate throughout the province is still heavy, and the disease is not checked.

Lorenz Tells Profits.—Dr. Adolf Lorenz is reported in the daily press to have said:

> I see it reported that I have made in this country $160,000. Now, as a matter of fact, I got one fee of $30,000 in Chicago, and in the four months I have been here I have earned just $30,000.

Want Clerks in Pension Office.—The commissioner of pensions desires to appoint twenty-five physicians in the next three months, as clerks and copyists in the pension office at salaries of from $900 to $1,000 a year. Only graduates of medical schools will be accepted in the examination, which is to be held January 27.

Want Panama Canal Physician.—The New York Academy of Medicine adopted the following resolutions, Dec. 18, 1902:

Whereas, It is well known that the previous excavations for an Isthmian Canal have been attended with a large amount of illness and a heavy mortality, due mainly to malaria and to yellow fever,

And, Whereas, Recent discoveries as to the causes of these diseases have enabled medical officers to control their ravages to a marked degree;

And, Whereas, The success which has crowned medical efforts in Cuba in apparently abolishing yellow fever, is another evidence for the belief that if proper hygienic precautions are taken at Panama and at other situations along the route of the Canal, the death-rate of the past can be much decreased or made to disappear. It is therefore

Resolved, By the New York Academy of Medicine that in its judgment the amplest powers should be given to the medical officers in charge of the sanitation of the Canal, and that to attain this end a medical officer should be a member of the Commission which the President of the United States is authorized to appoint to conduct the affairs of the proposed Canal.

It Is Furthermore Resolved, That the Secretary of the Academy be instructed to forward this preamble and resolutions, duly signed, to the President of the United States.

CANADA.

Canadian Hospital Tent Adopted by England.—The imperial government has adopted the Canadian hospital tent, which is the joint invention of Surgeon-General Neilson and Mr. Joseph Berry of Ottawa. Lord Kitchener saw the tent in South Africa and was delighted with it.

Personal.—Dr. A. E. Garrow, Montreal, will sail shortly from New York for Germany to spend several months in study. ——Dr. G. A. Charlton, Montreal, has been appointed resident physician of the Ottawa Isolation Hospital, and will enter on the duties of his office early in January.——The professors and lecturers of Bishop's Medical Faculty tendered a dinner at the Windsor Hotel one evening last week to Dr. Casey A. Wood of Chicago, a graduate of that institution, and at one time professor of chemistry and afterward of pathology.

Annual Meeting, National Sanitarium Association.—At the annual meeting of the board of trustees of the National Sanitarium Association, December 20, in Toronto, the report of the physician-in-charge, Dr. J. H. Elliott, for the official year just closed, showed that the past was the most successful year in the five years' history of the institution. During the five years 612 cases have been treated, and Dr. Elliott reported that during the past year 85 per cent. had apparently been cured or the disease arrested, while but 10 per cent. failed to improve. An important announcement was made by the secretary that a third institution was shortly to be erected near Toronto, and a fourth is under consideration to be established on the Pacific Coast.

FOREIGN.

London Fears Typhoid.—An increase in typhoid fever in London is reported. The unsanitary conditions of the city add to the fear of an epidemic.

Plague in Mexico.—Bubonic plague is said to have appeared at La Paz, Guaymas, Mulje and Mazatlan, all on the Pacific coast of Mexico. A score were reported dead December 22 and many were dying daily. A government commission is making an investigation as to the identity of the disease. Quarantine is being observed.

Leprosy in Norway.—The official statistics state that the number of lepers in Norway has fallen from 688 to 577 since 1895. Of the 533 in the three lepers' asylums, 187 have died, and 45 have been dismissed. The average duration of the disease was 18.2 years; for the form with nodules only 12.2, and for the nervous form 26.6.

Munich Vital Statistics to Be Dropped.—The local medical business organization at Munich petitioned to have postage supplied for the vital statistics sent in by physicians. As this request was denied, the physicians unanimously decided to abandon the task of supplying the statistics of morbidity, commencing with the New Year. At the same time they announce that they are ready to resume the task if the authorities should become convinced of the value of well kept vitality statistics sufficiently to bear the expenses.

LONDON LETTER.

Memorial to the Late Professor Virchow.

An inaugural meeting to promote in this country the memorial to the late Professor Virchow has been held under the presidency of Lord Lister. He said he thought that, as a rule, monuments to the departed should be made, if at all, by the nation which gave them birth, but there were exceptions, as in the case of Pasteur, whose work had benefited all mankind, and so with Virchow. A committee was formed of men of eminence.

Digestion in Plants.

Professor S. H. Vines has made some exceedingly interesting investigations into the digestion of plants. A year ago he gave the Linnean Society an account of some observations on the action of the enzyme, which not only possesses the property of peptonizing the higher proteids (e. g., fibrin), but also decomposes the proteid molecule into non-proteid nitrogenous substances, such as leucin. Since then he has investigated several other plants: Pineapple juice, cocoanut milk, melon, cucumber, tomato, marrow, grapes, pears, oranges, bananas, leaves of lettuce, green peas, onions, potatoes, cabbages, mushrooms, and turnips, and found them to be proteolytic.

The Plague.

INDIA.—During the three weeks ending October 18, 25 and November 1, the deaths from plague in India numbered 10,730, 10,494, and 8,915, respectively. Precautions are being taken against the inroad of plague on Delhi during the approaching durbar, and a large medical staff has been appointed to the inspection of stations on the railways leading to the city. With each surgeon a lady doctor has been wisely appointed to assist in the inspection. Extensive inoculation against plague has been temporarily suspended in the Punjab, as the imperial laboratory is incapable of supplying the requisite quantity of serum. It is stated that 10 persons have died in consequence of the serum with which they were inoculated being contaminated. The contamination was due to the changes suggested by the plague commission in the methods of preparation. Meantime the operations of prophylactic inoculation are suspended pending the preparation of an adequate quantity of a reliable serum.

EGYPT.—During the week ending November 16 one fresh case of plague was reported.

CAPE OF GOOD HOPE.—No case of plague in Cape Colony during the week ending November 1, the colony has been entirely free from plague since September 25, when the last patient died at Port Elizabeth. As late, however, as October 31 plague-infected rats were found at Port Elizabeth,

MAURITIUS.—During the weeks ending November 13, 20 and 27 the number of fresh cases of plague amounted to 23, 30 and 17, respectively, and the deaths from the disease to 14, 21 and 12.

PARIS LETTER.

Vallas' Report on the Treatment of Tetanus.

A most interesting report on the treatment of tetanus was made by Dr. Vallas of Lyons at the Congress of Surgery held in Paris a few weeks ago. He showed how the experiments of Carles and Rattone demonstrated the infectious nature of the disease, how Nicolaïer and Kitasato isolated the pin-shaped microbe, and showed that it was found in the earth.

In 1890, six years after the discovery of the microbe, the toxin was isolated by Faber, and later Vaillard showed that other microbes helped the bacillus, and that in ordinary conditions phagocytosis was a sufficient protection. Three methods of treating tetanus were to be considered: the classical treatment, that by the serum Behring-Kitasato, and Baccelli's method of carbolic acid injections. The first consisted in complete isolation and silence, and the use of large doses of chloral, as much as 10 or 12 grams being given in 24 hours. Amputation was permissible when the condition of the limb as the result of an accident might seem to plead for such a course.

The Behring-Kitasato treatment was discovered in 1890, and three different forms of serum are now employed, Behring's, Roux and Vaillard's, and Tizzoni's, which is a dry extract which is treated with water before being injected. Behring's method is used to determine the strength of a given serum and the unit consists in the amount needed to immunize a gram of white mouse against a fatal dose of toxin. The serum is not antitetanic, but antitoxic, so that it does not destroy the microbe, a fact which shows the importance of treating the wound most thoroughly. The preventive value of the serum was demonstrated by Nocard in 1895. 375 animals which were likely to take tetanus on account of a wound were inoculated and not one was affected by the disease, whereas 55 cases were seen among animals which were not injected.

In 1897 the same experiment was carried out on a larger scale, and 2727 horses were treated in this manner, and not one was affected with tetanus; 259 cases of tetanus were seen at the same time by the same veterinary surgeons. The result of this is that, as Dr. Landouzy has said, to wait for the onset of tetanus in a suspicious case is a mistake, and it is a rule to act when there is any possibility of infection. An injection should be made the first, third and tenth days. If the wound is not healed, it is well to make still another injection of 10 cubic centimeters. When tetanus has set in, the serum is not at all as efficacious. Kitasato lost his first case, but Tizzoni had eight successes out of 8 cases. In 1893 Roux and Vaillard had already 7 cases, with 5 deaths. There is one fact, which has been clearly demonstrated, it is that the injections are quite harmless. Dr. Vallas has been able to collect 373 cases, with the following results: Incubation of 10 days: 141 cases, with 80 deaths, which makes a percentage of 57 per cent. Incubation of more than 10 days: 118 cases with 24 deaths, or 20 per cent. Incubation not determined: 114 cases, with 41 deaths, or 36 per cent. These figures show that out of a total of 373 cases there were 145 deaths, or 39 per cent. Lockjaw is just as pernicious as ever in infants, and in women during the puerperium. If one compares this with the mortality seen in former days, 70 per cent., one is obliged to admit that there has been a noticeable improvement; 30 to 40 grams should be injected daily, until there has been a noticeable change.

There is a case on record of a negro who took 1800 grams. Intravenous injections have been found very useful in certain cases, and seem devoid of danger. As for intracerebral injections Dr. Vallas does not favor them at all. Baccelli's method consists in the daily injection of 30 to 40 centigrams of carbolic acid, in a 2 to 3 per cent. solution or a 10 per cent. solution in oil. This treatment, which has been applied more especially in Italy in some 80 cases, has been followed by a cure in all but 8 cases. Opotherapy, as formulated by Wassermann and Takaki, does not seem to be justified by the experiments carried out in the laboratory. As for peroxid of hydrogen, and persulphate of soda, the results following the use of these drugs are good, but the number of cases is very small.

Steiner has furnished statistics showing how the different serums have worked, and it would seem that the number of cures was greater in Germany and America, which may be due to the serum being used in lighter cases. In the discussion that followed Dr. Lucas Championnière said he considered intracerebral injections as quite innocuous, amputation was useless, and preventive injections had stopped an epidemic in his service some wears ago. Other physicians felt that this method was not to be absolutely condemned. Dr. Schwartz of Paris had 8 cases of lockjaw in his service from 1890 to 1898, and with an equal number of cases since then which were injected, he had only two cases, one who came in with the first symptoms already apparent, and the other who had not been injected.

Correspondence.

An Escaped Criminal Wanted.

DENVER, COLO., Dec. 22, 1902.

To the Editor:—Inclosed please find photograph of one of the rankest medical impostors that I ever heard of. His right name is Edward Rietzel and his parents live at 92 Crystal St., Chicago. In 1891 he was convicted under the name of Fox for grand larceny and sent to the Reformatory at Pontiac. He was let out on parole and next was heard of in Niles City,

Mich., in connection with the so-called St. Luke's Hospital of that place, where he assumed the name of Dr. Geo. A. Elliott, having stolen the diploma of Dr. Geo. A. Elliott of Leamington, Ont., who graduated in 1896 from the Medical Department of the University of Toronto.

At that time this bogus Elliott had a wife by the name of Adele Cornely, who was a graduate of a Swiss College of midwifery. Before going to Niles City he went under the names of Ralston and Ruleson. From Michigan he was next heard of in Kansas City, Kan., where he ran an abortion shop in the guise of a gynecologic hospital. Early in this year he presented this genuine diploma to our board and soon after began his nefarious practice in this city. In a little while he and his wife Adele Cornely were arrested by the federal authorities for sending abortion literature through the mails. She forfeited her bond and is now in Geneva, Switzerland, and it is believed that her arrest was a scheme on his part to get rid of her, he not thinking he would put his foot in it as well.

Between the 15th and 20th of February, 1902, he married again to one Mary Kaurin of Chicago. What became of her I do not know. In July of this year he was married to one Dr. Mary E. Inman, who claims to be a graduate of the Boston School of Medicine. The dean of this school writes that no one by that name ever graduated from his institution. In October he lost an abortion case by sepsis and hemorrhages, and was arrested under the charges of committing abortion and murder.

He was released on a $5,000 bail which he forfeited, having gone to parts unknown.

In the interest of the profession I beg of you to use this data and photograph in publishing an article in THE JOURNAL that may assist in his recapture. I may further add that the first thing that aroused my suspicion that he was not a graduate of the University of Toronto was his making application to the State Eclectic Medical Association, which was very queer if he belonged to a regular school.

I received a letter to-day in which it is stated that Dr. Egan has knowledge of this man's Chicago record, and you may be able to get direct from him some additional facts.

Thanking you in advance for extending me the courtesy of publishing this man. Very truly yours,

E. D. VAN METER,
Secretary Colorado State Board of Medical Examiners.

NOTE.—The Chief of Police of Denver furnishes the following data: Age, 29; height, 5 ft. 6 in.; weight, 136; dark complexion, hair and eyes; teeth good; German nationality; he may have his mustache off; he is with a woman who he says is his wife; wanted for murder at Denver.

A Side Light on Ethics.

To the Editor:—Apropos of the Code of Medical Ethics recently published in THE JOURNAL, it has occurred to me that we are very foolishly shutting our eyes and closing our ears to the low standard of ethics practiced by the medical profession in America to-day. This is an age of commercialism. It has planted itself as firmly in the profession of medicine as in the department stores. This commercialism is a menace to the high standing of our medical men; it handicaps the good we might do for humanity; the reform we might accomplish; the respect we might command. Year by year the standard of ethics and ideals is lowered. At present we stand almost at the head of the list, in the eyes of the world, of professional jealousies. The musician and the medical man rank side by side in their bickering and in their enviousness. Newspaper men and the laity in general recognize it and laugh good-naturedly at our expense.

The public know, in a vague way, that there is an indefinable thing called medical ethics. They envelope it with the mysticism that the uninitiated envelope the masonic rite. They know that the profession regards the physician who advertises in the advertising columns of the daily papers as a quack, but that if a man have sufficient reputation he may insinuate his name with impunity in the main body of the newspaper—this they understand is immeasurably more delicate, and certainly tells in a more clever fashion, while the "small fry" dare not be so bold as to resort to either of these methods. The laity, accordingly, are fairly settled in the belief that the unpardonable sin is for the professional man to insert his ad. among the advertisements, and they thus differentiate between the man of reputation and the quack by the part of the paper in which his name appears. When the public comes in personal contact with many of our profession who are in good standing and with the successful "smooth quack" they are too frequently unable to detect any difference in their conduct.

I think I express the sentiments of the average medical man when I say that the recent graduate very soon takes on one of the characteristics of an animal called a bulldog. When that animal gets a bone, by chance or otherwise, if there is good meat on it he shows his teeth at the approach of another dog, and stands ready to fight for his rights. I am not a pessimist. It is my good fortune to have been associated in consultation, with few exceptions, with men who were ethical to a degree. I may add that when I have the privilege, I choose my consultant with as much care as though I were selecting a lawyer to defend me against a charge of murder in the first degree.

It is easy enough for the man of means and of some social prestige to adhere to most of the Code of Ethics. But what of the man who starts his professional life with a wife, perhaps a young family, and a small bank account? Can he afford to be ethical in the face of an empty pantry, and scanty clothing? How many of us are strong enough to do unto others as we would be done by, when, as David Harum says, the other fellows are doing us, and doing us first. What incentive is there for the young specialist to keep faith with his Code, when men who have risen to the very top of the ladder in their respective lines are flagrant violaters of the essentials of medical ethics?

May I illustrate a case in point: For the past few years I have been the family physician in a certain household. After urgent persuasion I gained the mother's consent to make a local examination for a persistent and suspicious hemorrhage from the uterus, with the result that I unhesitatingly declared she be sent to the hospital, and after more thorough investigation probably submit to a hysterectomy for cancer. The family were quite satisfied until a near relative insisted on consultation with a noted surgeon who had performed an operation on a sister. The surgeon in question stands in the very front rank of our profession. I called him up by telephone and explained the situation. I agreed to have him see my patient at the hospital he desired, and at a time to suit his convenience. After we had finished our consultation, my consultant, without asking my permission, called the family together, gave his diagnosis, his treatment, and his prognosis. He then proceeded to set the time for operation, and graciously invited me to be present as an on-looker if I so chose. However, as the invitation was suggestive of my being asked to officiate at my own funeral, I did not go. Previous to the consultation the husband of my patient had asked what my charges would be if I did the operation. He was worth from $25,000 to $50,000, but knowing the family's tendency to "nearness" I felt I must be modest if I were able to keep my bone. I answered "one hundred dollars!" The husband shook his head. "This big surgeon my sister wants us to call in would not charge me as much as that." I learned afterward that my consultant of large fame actually did the operation—hysterectomy—for $40.

I mention this case because it is typical of the point I wish to bring out. My consultant is a good man. His alma mater is proud of him, so is his state, so is his country—so am I for the advances he has made in surgery. He is an honor to his profession. He is one of the men whom an esteemed French confrère had in mind when he wrote me enthusiastically: "I have visited every great medical center in the world, and I have never yet seen the equal of your surgical clinics in Chicago. It is magnificent—the material, and the men you have to operate on it." My consultant is an overworked man; he has more operations than he can do. Patients wait their turn for him. He was not tempted to take my case away from me, nor unwilling to share the honors, if there were to be any, of the result of the operation, because he was in need of money. He is not a grasping man; his fee of forty dollars would give the lie to such an accusation. It is said he stood at the head of his class in the average of his studies, but he certainly was never compelled to take an examination in medical ethics. He is too busy now to think about such a trifling thing as ethics. He may have seen the word written somewhere. He may possibly glance over the Association's revision of the Code, but it will never occur to him during his eminently successful and busy career to drink of the spirit of these rules and regulations. He is too old to learn. Hundreds of men will continue to witness his operations and to learn what they may from him, but if they have good sense, they will avoid him assiduously as a consultant. Meanwhile he will unconsciously continue, day after day, to go on with the gentle art of dampening the youthful ardor of the enthusiast who leaves his alma mater with high ideals and ethical aspirations. He will make these men smile at the mention of Flint on Ethics, and have thoughts unfit for publication when he reads "Of the duties of the physician in regard to consultations."

In Article I, Section 2, the revision of the Code admonishes the physician to "entertain a due respect for those seniors who, by their labors, have contributed to its advancement." Be assured the younger man will never fail in veneration for his senior, if the latter is worthy of it. The ethical man of reputation will ever have bestowed on him his due—and more.

The discourtesy existing in many of our medical societies in America is proverbial, and so rough is the abuse at times, and so unwarrantable the insults, that many a man who would

gladly give his little to "enrich the science" with some new thought or experience, shrinks from a public encounter with his medical associates. Allow me to detail another personal experience. At the suggestion and invitation of a most ethical consultant, I presented, a few months ago at one of the medical societies, a simple apparatus for the convenience of putting up, at right angles, a fractured leg of an infant. The history of my case in brief was this: After a difficult and tedious labor in a primipara, aggravated by a breech presentation, I delivered my patient of a living eight-pound child. As a last resort, when the anesthetic had to be stopped on account of a very rapid pulse, and a threatened cessation of respiration, I used the blunt hook. Stimulants were given hypodermatically, and artificial respiration was being performed while I made one last attempt to deliver the child with the aid of that instrument. I succeeded, and at the same time fractured the upper third of the thigh during the process. Fortunately, the mother and child made a good recovery. At my request the parents consented to bring their babe to the medical society on the evening that I was to exhibit my apparatus. I gave a brief outline of the case from the *time of fracture*, merely mentioning that the accident had occurred from the use of the blunt hook during delivery. I exhibited the *x*-ray photograph of the broken fragments of the femur, the little apparatus that had served its purpose so well, the various photographs of the infant while in the fracture bed, and the undeformed child. As soon as I had finished my remarks, and while the baby, held in the mother's arms, was being exhibited, one of the most noted members of the society sprang to his feet and began to denounce, in very scathing terms, my use of the blunt hook. Under the most favorable circumstances the discussion of the use of the blunt hook was hardly in order. The man criticising me knew nothing of the emergency of the obstetrical case. Moreover, I came there solely for the purpose of presenting a simple and effectual means of suspending the fractured leg at right angles, and in the hope that even the little I had to offer might serve its purpose of "enriching the science," no matter how insignificant that enrichment might be. No words can express my consternation at the sudden turn of events, especially when the tirade of criticism directed against me was made in the presence of my small patient's mother and father. Up to this time the family had considered me, like Tommy Sandys, "a wonder!" But here was a revelation for them. I was caught red-handed in an unscientific and unpardonable error—had I conducted my case properly I would not have broken their baby's leg. It is hardly necessary to add, that I am not, at present writing, their family physician. The episode in the medical society may or may not be entirely responsible for their change of doctors. Be that as it may, I should certainly feel much easier if I were ever to exhibit another patient before the same society, if the individual were deaf, dumb and blind.

The point I wish to emphasize is this: The doctor who "called me down" before my patient was a thoughtless man. If he reads this article he will probably not remember the incident. He had never met me personally, either before nor since. There was no malice, no evil intent, and I doubt if the majority of men present at that meeting gave the incident even a passing thought, so little would such a gross breach of ethics attract attention at the present time. But I ask in the name of all that is lofty in medicine, what an effect such an affair would have on a young fellow who had just started out in his practice, and who could not see how he was going to get money enough together to buy a winter overcoat. A young fellow, who, by the loss of that one family and the everlasting harm they could do him—if they so had a mind, was compelled to give up the weary fight, and perhaps accept a position offered him by a chemical house as traveling salesman. I ask in all fairness why there should not be adequate punishment meted out to such men—no matter whether the blunder be of thoughtlessness or malice. Younger men must have protection from these onslaughts if it is expected of them to "entertain a due respect for those seniors, who by their labors, have contributed to its advancement."

Article IV, Section 4, says that "Consultations should be promoted in difficult cases, as they give rise to confidence and more enlarged views in practice." Theoretically, this is a fact. But I speak for the younger, struggling practitioner when I say I know in a great number of cases that if the physician in charge be in any degree a sensitive man, he is a moral coward when it comes to consultations. This is especially so if he is not personally acquainted with his consultant. Too often, on his senior's arrival, he waits breathlessly for—whatever damage this man who has made his mark in the world, may see fit to deal him. We all realize the fact that it is not the rule for the consultant to be careful not to walk into the sick-room first. He frequently begins to examine the patient at once. He practically ignores the attending man, proceeds to interview the family, gives his diagnosis, prognosis and treatment, and finally leaves behind him doubts in the family, and a lack of confidence in their attending man. He not rarely does more harm than good.

Before we attain as high a regard in the eyes of the public as we have ambition for, we must set about casting these motes from our eyes. The older and more experienced man must never withhold a helping hand to the beginner. He must guide, protect, advise him, as he would his own son. He who reaches the summit of his profession must step on the center of the platform, with the lime-light full on him. He may err with impunity, he may have his weaknesses, his foibles as before he gained his fame, but he must never be found wanting in that sentiment which underlies and permeates the Golden Rule. Medical ethics after all, are simply the embodiment of that rule, and it must be the religion of the medical man. Not until our profession has been delivered from the chaotic state of its present ethics can we hope to stand together in a body for the good of present and future humanity. And until then it is a waste of space to insert Article II on the "Obligations of the Public to the Physician." We have no right to ask the public to respect us when we do not respect each other. We must turn out from our colleges as indispensable qualifications, men who are ethical to a degree. A majority of us today must turn over a new leaf in our attitude toward each other. We must pull up the commercialism, root and branch, that is eating into our vitals like a cancer. We must never be too busy, too overworked, too successful, to do unto others as we would wish them to do unto us.

Granted that the public should be enlightened so that they may more truly appreciate the difference between the spurious and the trustworthy qualifications of the medical man, be it also demanded that they be taught the law of medical ethics. They should be able to detect the unethical consultant as quickly as the physician in charge. They should be taught to respect these ethics. And they should also be taught that the consultant who transgresses upon this Code is not the man to whom they owe obligations, consideration, or respect.

As an ethical body, in spite of our multitudinous differences, we can join hands. We can aid in repressing wrongs, physical and moral. We can successfully establish reformations. Isms, false sciences, charlatanism, will gradually die out from lack of patronage. There will be no limit to our potency for good.

I venture the statement that I can send one of my patients on whom I have recently performed an abdominal section, the rounds, in alphabetical order, to the physicians whose names appear in the Blue-Book, or official directory, that she can go to each one of these men with a like tale—e. g., that she has recently undergone an operation by me, that she is no better, that she doubts as to whether I was honest with her in what I said I did, that she would like to be examined and have them give her their opinion as to the nature of the operation I performed. Barring some of the men who know me personally, I think I do not exaggerate when I say that 3 per cent. only might ask if I had been paid and discharged from the case. I doubt if it would occur to 2 per cent. to find out if I were a physician in good standing, or if they had a telephone in their office, take the trouble to call me up before proceeding to grab my bone because I was not looking—especially if there were any meat on it in the shape of currency.

When such a state of affairs exists, I can readily believe that many of the men who read our revised Code, may think it worthy of emanating from the pen of our Mark Twain, and con-

sider its fitness to be entered for a prize in the contest of the "Funniest thing I have ever read."

This is a busy, busy world, and so long as we, as a body, adopt the present method of business for personal gain, no matter at whose cost, let us not be so cowardly as to ask the public for any more consideration than they give to other business men. We are no better nor no worse than the rest of tradesmen. Our religion is his religion: "Every man for himself and the devil for us all."

If we are not content with the present condition of affairs, we must begin at the very beginning. We must impress on the applicant for admission to our medical schools, that something more is required of him than his fee, and satisfactory credentials as to his literary attainments. He must be capable of comprehending and appreciating the sentiments and essentials of the Golden Rule. As a freshman, while vivid conceptions are made on his mind, he should receive a short but impressive course of lectures on medical ethics, and he should be examined on these lectures at the close of his freshman year, and he should not be allowed to continue with the remainder of his studies until he had passed a high per cent. in ethics. This should be continued during the remainder of the prescribed years of his college course. The strictest ethical conduct should be observed between professors and instructors. When a patient is sent from one department to another, or from one clinic to another, or from one college to another, the ethics of the man or men in charge should be above reproach and of such a nature as to impress every student present. If there is the slightest chance of the patient having been attended by some physician and a previous diagnosis having been made, the last man whom the patient appeals to must withhold his opinion entirely, or at least he must give it in such a manner that the patient can not interpret that there has been a criticism of his previous medical attendant or attendants.

There is a way in which one professional gentleman can disagree with another professional gentleman, or take serious issue with him, which is a source of inspiration to the student, and stimulates him with a healthy desire to hear both sides of the question, and no matter which view appeals strongest to the student's mind, he has a profound respect for both gentlemen. There is a broad-minded, courteous, refined way of differing from another, and there is a sneering, narrow-minded way not unlike the manner in which one butcher runs down another butcher's grade of meat, or his methods of business. We would be more honest with ourselves if we either entirely did away with a Code of Ethics and made no pretense of being ethical, or obeyed it to the letter. We must be a body of professional men with high aims and lofty principle, or we must be a body of first-class, shrewd business men.

We can accomplish the former much-to-be-desired condition of affairs only by educating our men while they are in college, and thus giving them an ethical conscience, as the up-to-date medical man acquires the "aseptic conscience." You can mark the man who has recently taken up the aseptic theory, and the man who has had it drilled into him from the time he was a freshman. It is second nature for the drilled man to hold his clean hands in the air until he is ready to touch the field of operation. He never forgets. He never touches anything that is not sterile. When his hands are cleaned they go as automatically as a soldier salutes when his superior officer passes him. If we would turn out ethical men from our schools we must train them with as much care as we drill them in their technic of asepsis. His ethics must become a part of him—second nature.

The consultant must fully understand that his influence is incalculable either for good or for evil. He must appreciate the fact that he often has it in his power to turn the tide of a young fellow's career. That he is responsible for the bulldog tendency of to-day. It is he who is capable, in a great measure, of inspiring the younger men to live up to the high ideals of their profession, and to be a worthy part of a body of men who can if they will, accomplish more good for humanity than any other profession or factor. On the contrary, he does his part in damning the hard-pushed, recent graduate, until he finally gives up the fight and goes into another business, or worse yet, joins the ever-increasing army of men who have graduated from medical schools in good standing, and who become a menace to society by inserting medical advertisements in which they assure the public of "guarantees" and "sure prevention."

The alumni from every reputable medical college must remember their alma mater with affectionate regard, and they must be made to feel that the men connected with their alma mater are their foster fathers, and if they are deserving, they can depend on them always for encouragement, professional assistance, protection and for ideal consultation. We must add another chair to our medical course, and the man who is at the head of that chair must be possessed of an "ethical conscience."

ROBT. T. GILLMORE, Chicago.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

CINNAMIC ACID IN TUBERCULOSIS.

SCRANTON, PA., Dec. 20, 1902.

To the Editor:—On page 1623, last issue, you refer to the cinnamic acid treatment of tuberculosis and refer to Krause having used Landerer's directions or formula. Will you kindly furnish me with the formula for the intravenous injection of this acid?

E. ZIEGLER BOWER.

ANS.—Landerer's method, as we understand it, is the intravenous injection of sodium cinnamate dissolved in sterile salt solution. He uses 1/10 to 1/3 grain of sodium cinnamate at first and gradually increases the dose until several grains are given at each injection. The literature of the subject is extensive. One of the latest articles is that by Dr. Wm. J. Robinson completed in the December number of *Merck's Archives*. It gives a good bibliography of the subject. Consult also Landerer's book on the subject. We can not inform you where to obtain it.

LEGAL ENTRIES IN ACCOUNT BOOKS.

SAN FRANCISCO, Dec. 16, 1902.

To the Editor:—Do the entries made by conventional signs as explained in visiting lists (such as the visiting list of Blakiston) have a legal validity or what constitutes a legal entry in a visiting list?

GEORGE GROSS, M.D.

ANS.—The laws of states differ. As a general answer: The original entries should be itemized and intelligible, requiring no explanation, at least so far as amounts are concerned, if they are to be used as evidence.

LENGTH OF QUARANTINE IN SCARLET FEVER.

SOUTH DAKOTA, Dec. 13, 1902.

To the Editor:—1. Kindly let me know through the columns of THE JOURNAL if you think a quarantine of ten days sufficient for even the mildest case of scarlet fever.

2. Also give a diagnosis of the following, if you can, from the symptoms. We have had an epidemic and there has been a dispute as to the diagnosis. Fever from 12 to 24 hours, after which a rash develops which is first vesicular, but inside of twenty-four hours some of the pimples become pustular, but the most of them do not develop pus and inside of three or four days they begin to dry up and in a few days more the crusts drop off, leaving a red spot which disappears in a week or ten days. In some of the cases there has been a little sickness of the stomach.

This has been diagnosed variola by some of the physicians, with which diagnosis I can not agree. X.

ANS.—1. A quarantine of ten days is decidedly under the limits. 2. We can not give a diagnosis from the data given.

RECIPROCITY WITH NEW YORK.

WELLSVILLE, N. Y., Dec. 13, 1902.

To the Editor:—Will you kindly inform me through your journal what states acknowledge a New York State license? Will Illinois?

B. A. BARNEY.

ANS.—We believe that no state reciprocates with New York since New York does not recognize the licenses of any other state.

Marriages.

EDWARD E. MOORE, M.D., to Miss Ida Morley, both of Chicago, December 13.

F. S. PECK, M.D., to Mrs. Annie O'Howell, both of Stillwater, Okla., November 26.

NATHANIEL WELSH HICKS, M.D., to Miss Mary Thomas Stroud, both of Florence, S. C., December 3.

FRANK F. NEWELL, M.D., Burlington, Wis., to Miss Gretchen Leis Land of Waukesha, Wis., December 10.

CHARLES FRANCIS READ, M.D., Grand Rapids, Mich., to Miss Ethelwynn Eaton of Beloit, Wis., December 16.

Deaths.

Joseph R. Laine, M.D. University of Buffalo, 1876, a member of the American Medical Association, died at the German Hospital, San Francisco, December 15, from heart disease, after a long illness, aged 56. He first practiced in Peoria, Ill.; then moved to Nebraska, was an acting assistant surgeon in the Army, and later moved to California, residing first at Sacramento and afterward at San Francisco. He was for eight years a member and secretary of the State Board of Health; he was one of the organizers of the College of Physicians and Surgeons, and its president until 1899. He was also lieutenant-colonel and assistant surgeon-general in the National Guard of California.

Jacob M. Kraus, M.D. University of Buffalo, 1889, a member of the Buffalo Academy of Medicine, the New York State Medical Association, and the American Medical Association, died at his home in Buffalo, December 19, after a lingering illness, aged 36. He was a physician of marked ability, and at the time of his death was on the medical staff of the German Hospital, and physician to the Erie County Penitentiary. Resolutions expressive of sorrow and respect were passed by the hospital staff and the societies to which he was affiliated.

John B. Crombie, M.D. University of Maryland, Baltimore, 1883, a member of the American Medical Association and a prominent physician of Allegheny, Pa., was struck by a locomotive and instantly killed, at Allegheny, December 22, aged 45.

Robert H. Moore, M.D. University of Louisiana, New Orleans, 1861, major-surgeon C. S. Army, for 25 years a resident of Hot Springs, Ark., and for six years coroner of Garland County, died at his home, December 15, after a long illness.

Mary Willits, M.D. Woman's Medical College of the New York Infirmary, 1898, first assistant physician at the State Hospital, Norristown, Pa., died at that institution, December 16, from cancer, after an illness of several months.

William P. Armstrong, M.D. University of Louisville (Ky.), 1857, formerly of Terre Haute, Ind., died at Jamestown, Cal., December 16, from heart disease, after an illness of one week, aged 73.

Malcolm Ethan Parrott, M.D. Jefferson Medical College, Philadelphia, 1883, died at his residence in Brooklyn, December 16, from Hodgkin's disease, after a long illness, aged 55.

Alexander Demby, M.D. Long Island College Hospital, Brooklyn, 1899, died at his home in Brooklyn, December 17, from appendicitis complicating typhoid fever, aged 23.

John M. Bowser, M.D. Medical College of Ohio, Cincinnati, 1878, died at his home in Goshen, Ind., December 19, from heart disease, after a short illness, aged 53.

Henry Bauer, M.D. Long Island College Hospital, Brooklyn, 1896, died at his home in Brooklyn, December 18, from meningitis, after an illness of one week, aged 27.

A. Wilber Hoon, M.D. Jefferson Medical College, Philadelphia, 1902, died at his home in Brushton, Pittsburg, Pa., December 16, from erysipelas, aged 25.

William A. Kidd, M.D. Western Reserve University, Cleveland, 1897, died from consumption at his home in Independence, Pa., December 11, after a long illness.

William B. Stevens, M.D. Jefferson Medical College, Philadelphia, 1891, of Nelson, Pa., died at Hartford, Conn., December 11, from Bright's disease, aged 37.

Samuel Daggy, M.D. a surgeon in the Union Army in the Civil War, died at his home in Philadelphia, December 15, from pneumonia, aged 79.

Frederick LeB. Brady, M.D. College of Physicians and Surgeons, New York, 1899, died at his home in New York City, December 20, aged 30.

Oscar F. Seeley, M.D. Rush Medical College, Chicago, 1868, died suddenly from heart disease at his home in Climax, Mich., December 18, aged 72.

Henry N. Jones, M.D. Dartmouth Medical College, Hanover, N. H., 1840, died at his home in Kingston, Mass., December 18, aged 87.

Francis M. Davis, M.D. Texas Medical College and Hospital, Galveston, 1874, died at his home in Houston, Texas, December 16.

John S. Mason, M.D. University of Maryland, 1836, died at his home near Waverly, Sussex County, Va., December 16, aged 85.

J. Knox Barney, M.D. Washington University, St. Louis, 1874, died at his home in Weir City, Kan., December 12, aged 60.

James R. Douglas, M.D. Missouri Medical College, St. Louis, Mo., 1855, died recently at his home in Batchtown, Ill.

Robert W. Armstrong, M.D., died at his home in Baltimore, December 12, from heart disease.

Deaths Abroad.

Prof. Richard von Krafft-Ebing, the eminent psychiatrist of Vienna, died at Graz, December 22. Richard, Baron von Krafft-Ebing, Hofrath and Knight of the Order of Franz Joseph, was born at Mannheim in 1840. Among his masters were Friedreich at Heidelberg and Griesinger at Zurich, and soon after his graduation he was appointed assistant physician at the insane asylum of Illenau. At 32 he became professor of psychiatry at Strassburg, and later at Graz, and in 1889 was called to the same chair at Vienna. His manuals of criminal psychology, psychiatry and forensic psychopathology have passed through numerous editions, and his contributions to the literature are quoted everywhere. The thirtieth anniversary of his career as a professor was celebrated March 11, and a jubilee number of the *Jahrbücher für Psychiatrie und Neurologie* was presented to him, adorned with an exceptionally fine portrait and containing twenty-five articles by Erb, Pick, Wagner, Von Jauregg and others. He delivered his last lecture March 6, as he resigned his post before reaching the age limit, for reasons connected with his health, and settled at Graz. He early recognized that psychiatry was in danger of following a false path, and was successful in leading it to its true place among the other special branches of medicine. To him more than to anyone else, perhaps, we owe the recognition of the close relationship between psychiatry and neuropathology.

Karl Nicoladoni, M.D., the well-known professor of surgery, first at Innsbruck and later at Graz. He was born at Vienna in 1847, and died at Graz, December 4, 1902. One of his first contributions to science was the successful relief of paralytic contractures by transplantation of tendons. His research on the spine in scoliosis is the basis for our knowledge on the subject, and he was also the first to describe the syndrome caused by torsion of the seminal cord, and to suggest orchidopexy. He was the inaugurator of the method of restoring a missing thumb by utilizing the second toe as a substitute.

M. Victorino, M.D., a prominent physician and surgeon of Rio. He was only 47 years old at the time of his death, November 9, but had been professor of surgery at his native city, Bahia, until appointed governor of the state, then senator, and finally vice-president of the republic of Brazil. His works on tropical parasitic affections have been translated into French, etc., and are frequently cited. He was also a prized contributor to the lay as well as to the medical press.

Ernst Bidder, M.D., a prominent physician at St. Petersburg for many years, professor of obstetrics and author of numerous works on this and allied subjects. He was the son of the physiologist, F. Bidder of Dorpat, where he was born in 1839.

Association News.

Rates to New Orleans Meeting.

Mr. Joseph Richardson, chairman of the Southeastern Traffic Association, has sent us Passenger Tariff Circular No. 1646 officially announcing rates for the New Orleans Meeting of the American Medical Association. From this we extract the following:

RULES AND REGULATIONS.

RATES.—One first-class fare for the round trip (minimum rate 50 cents) from all points south of the Ohio and Potomac and east of the Mississippi rivers.

DATES OF SALE.—May 1, 2, 3 and 4, 1903.

TRANSIT AND FINAL LIMITS.—Tickets will be honored for continuous passage in each direction with final limit 10 days from date of sale.

EXTENSION OF FINAL LIMIT.—Provided ticket is deposited in person by the original purchaser with special agent not later than May 12, 1903, and on payment of fee of 50 cents at time of deposit, final limit will be extended to a date not later than May 30, 1903.

The above rate and arrangement are respectfully tendered to connecting lines for basing purpose.

The following railroads are in the Southeastern Traffic Association:

Alabama Great Southern R. R.; Alabama & Vicksburg Ry.; Atlantic Coast Line R. R.; Atlanta, Knoxville & Northern Ry.; Atlantic & Birmingham R. R.; Baltimore & Ohio Southwestern R. R.; Blue Ridge Ry.; Central of Georgia Ry.; Charleston & Western Carolina Ry.; Cincinnati, New Orleans & Texas Pacific Ry.; Florida East Coast Ry.; Frisco System (K. C., M. & B. R. R.); Georgia R. R.; Georgia Southern & Florida Ry.; Illinois Central R. R.; Jacksonville & Southwestern R. R.; Louisville & Nashville R. R.; Macon & Birmingham Ry.; Macon, Dublin & Savannah R. R.; Mobile & Ohio R. R. R.; Nashville, Chattanooga & St. Louis Ry.; New Orleans & Northeastern R. R.; Norfolk & Western Ry.; Richmond, Fredericksburg & Potomac R. R.; Southern Ry.; Tennessee Central R. R.; Tifton, Thomasville & Gulf Ry.; Washington Southern Ry.; Western & Atlantic R. R.; West Point Route (A. & W. P. R. R. & W. Ry. of Alabama); Wrightsville & Tennille R. R.; Yazoo & Mississippi Valley R. R.

The Committee on Scientific Research of the American Medical Association is prepared to receive applications from gentlemen engaged in scientific research bearing on practical medicine or surgery. Five grants of $100 each will be given in support of such investigation. The results of the work in each case must be presented, either in abstract or complete, before one of the sections of the American Medical Association, preferably the Section on Pathology, at the next annual meeting, at New Orleans, May, 1903. All applications should be accompanied by a full statement of the applicant's previous work and training and his present facilities, as well as by a sufficient indication of the proposed or partly completed work to enable the committee to decide on the advisability of making a grant. [Signed] Alfred Stengel, Chairman, 1811 Spruce St., Philadelphia; William Osler, Baltimore; Ludwig Hektoen, Chicago.

Medical Organization.

Conference on Organization.

A meeting of the presidents and secretaries of the Illinois, Indiana, Iowa, Michigan, Minnesota, Missouri and Wisconsin state societies, and others interested in organization, was held at the University Club, Chicago, on the afternoon and evening of December 27. The following were present:

M. L. Harris and E. W. Weis, president and secretary of the Illinois State Medical Society; J. B. Berteling, president of the Indiana State Medical Society; James T. Priestley and V. L. Treynor, president and secretary of the Iowa State Medical Society; A. E. Bulson and A. P. Biddle, president and secretary of the Michigan State Medical Society; J. W. Andrews and Thos. McDavitt, president and secretary of the Minnesota State Medical Society; Woodson Moss, president of the Missouri State Medical Association; J. V. R. Lyman and C. S. Sheldon, president and secretary of the Wisconsin State Medical Society; N. B. Carson, president of the St. Louis Medical Society; W. A. Evans, president of the Chicago (Cook County) Medical Society; Robt. B. Preble, chairman Committee on Organization of the Chicago Medical Society; E. Fletcher Ingals, chairman of the Committee on Reorganization of the Illinois State Medical Society; D. S. Fairchild, chairman of the Committee on Reorganization of the Iowa State Medical Society; Leartus Connor and W. H. Haughey, chairman and secretary of the Council of the Michigan State Medical Society; James H. Reed and A. W. Alvord, Battle Creek, Mich.; H. P. Newman, R. R. Campbell, Harold N. Moyer, E. C. Dudley, C. S. Bacon, E. Wyllys Andrews, J. B. Murphy and others from Chicago and Frank Billings and George H. Simmons, President and Secretary of the American Medical Association.

At the afternoon session, after a brief review by Dr. Simmons of the reorganization of the American Medical Association and the relation of the latter to the state societies, the president of each of the state societies represented in the conference gave an outline of what had already been done in his state and what is to be accomplished in the future.

Faults in the plan of certain of the state societies already reorganized were pointed out and recognized. Four of the states represented reorganized at their annual meetings this year, viz., Illinois, Michigan, Minnesota and Missouri. The plan adopted by the Michigan State Medical Society was shown to be almost ideal. The councilor system, with larger functions than are given in the constitution adopted by the Committee on Organization of the American Medical Association, and endorsed by that body, were especially commended. Indiana, Iowa and Wisconsin will act on the matter of reorganization at the coming meeting.

Dr. N. B. Carson of Missouri, Dr. E. Fletcher Ingals of Illinois, Dr. W. H. Haughey of Michigan and others took part in the discussion in the afternoon session.

The evening session consisted of a banquet, followed by a continuation of the conference. Dr. Billings spoke of the many benefits to be obtained through thorough organization. Dr. Harris showed the advantages of the new plan of organization as regards dues, and emphasized the fact that the dues would be much lower for the individual, and at the same time a larger amount would be realized, because a larger number would contribute.

Dr. Connor discussed the idea of a state society issuing its transactions in monthly journal form, rather than in the old method. He spoke of the practical results in Michigan from its journal which was established five months ago, and urged other state societies to do likewise. He said that the time had come when the members of the medical profession were demanding journals published in their interests, and not solely in the interest of the proprietary medicine men.

Dr. Biddle spoke of the card index system of keeping a record of licensed practitioners. He called attention to its simplicity and effectiveness and how easily the individual's record could be arranged to follow him wherever he might go.

Dr. Simmons especially urged that in the plan of organization adopted in any state the fact should not be lost sight of that one of the objects to provide for is that of obtaining information in regard to every man licensed to practice in every county, so that there shall be no one, whether a member of the organization or not, whose medical history shall not be on file on a card index in the office of either the secretary of the county or of the state society. In combining two or more sparsely settled counties into one society, a vice-president or some officer for each county should be provided for, whose duty it should be to represent and make reports for such county. He also called attention to the great advantage a record of every practitioner would be in preventing the registration of men in a state who had forfeited the right to practice in another state, if the organization co-operated with licensing boards.

Dr. Moyer spoke of the medicolegal, or medical defense function which had been adopted by the Chicago Medical Society. The object is not alone to protect members in malpractice suits, but in other ways to benefit them.

Drs. Evans and Preble talked on organization in large cities, and explained how Cook County—Chicago—had been divided into twelve districts, with a branch society in each district, and these again subdivided for work. Over four hundred new members have already been received in the Chicago Medical Society this winter and it is expected that by the annual meeting the membership will have reached two thousand.

Dr. Carson spoke of the trouble that had prevailed in St. Louis and of the better conditions already developing.

Many others spoke briefly and at nearly midnight the conference adjourned. It is believed that much good will result from this gathering, as a better appreciation of what is being attempted and a better knowledge of how to carry on the work and meet the difficulties was had by all.

Highland County (Ohio) Medical Society.

This society was organized at Hillsboro December 17, through the efforts of the councilor of the district, Dr. Brooks F. Beebe, Cincinnati, and of Dr. John C. Larkin, Hillsboro. There was once a society in this county but it has been dead for at least half a dozen years. Our reporter states that at the meeting for organization there were more physicians present than were ever before gathered in the county. Two-thirds of the regular physicians of the county became members and others who were unable to be present sent word that they would join at the next meeting.

The regular meetings will be held on the first Wednesday in January, April, July and October. The following is a list of the officers for the ensuing year: President, H. A. Beeson, Leesburg; vice-president, H. A. Russ, Hillsboro; secretary, J. C. Larkin, Hillsboro; treasurer, A. H. Beam, Hillsboro; delegate, W. W. Glenn, Hillsboro.

Societies.

Salt Lake County (Utah) Medical Society.—At the annual meeting of this society, held in Salt Lake City, December 8, Dr. Alexander C. Ewing was elected president; Dr. James N. Harrison, vice-president, and Dr. Henry La Motte, secretary, all of Salt Lake City. Dr. Augustus C. Behle, Salt Lake City, was unanimously re-elected secretary.

Iowa Central State Medical Society.—The annual meeting of this society was held in Marshalltown, December 9. The following officers were elected: Dr. Nelson Merrill, Marshalltown, president; Drs. E. W. Jay, St. Anthony, and Harry C. Willett, Whitten, vice-presidents, and Dr. Matthew U. Cheshire, Marshalltown, secretary and treasurer.

New Haven (Conn.) Medical Association.—This association will celebrate the one-hundredth anniversary of its organization, January 5 and 6. Commemorative addresses will be delivered by Drs. William Osler of Baltimore, and Dr. Francis Bacon of New Haven, and a reception will be given in their honor. Tuesday evening the association will have its annual dinner.

North Texas Medical Association.—This society convened for its forty-fourth semi-annual meeting at Dallas, December 9, and continued in session 3 days. Waxahachie was selected as the next place of meeting. Dr. Jarrett T. Benbrook, Rockwall, was elected president; Dr. Charles W. Simpson, Waxahachie, vice-president; Dr. Hugh L. Moore, Van Alstyne, secretary, and Dr. Carey A. Gray, Bonham, treasurer.

Northwestern Ohio Medical Society.—The fifty-eighth annual meeting of this society was held in Findlay, December 11 and 12, with about 300 members in attendance. It was decided to hold the 1903 meeting in Toledo. The following officers were elected: President, Dr. John North, Toledo; vice-presidents, Drs. William B. Van Note, Lima, and Myron J. Ewing, Findlay; secretary, Dr. Albert S. Rudy, Lima, and treasurer, Dr. Theodore M. Gehrett, Deshler.

Medicolegal Society of the District of Columbia.—This society was organized in Washington, December 11. Its principal objects are to promote the enactment of medical legislation in the interests of the citizens of the District of Columbia and the discussion of all civic affairs of a medical and legal character, and to bring about social affiliation among physicians, lawyers, dentists, pharmacists, and veterinary surgeons of the District of Columbia. The election of officers was as follows: President, Dr. Robert Reyburn; vice-president, Dr. William D. Hughes; secretary, Dr. Charles M. Emmons; treasurer, Dr. C. Robinson, and attorney, Edwin Forrest.

BUFFALO ACADEMY OF MEDICINE.

Regular Meeting of the Section on Pathology, held Dec. 16, 1902.

Dr. Irving P. Lyon in the Chair.

Uncinariasis.

DR. CHARLES WARDELL STILES, zoologist to the United States Public Health and Marine-Hospital Service of Washington, D. C., delivered an address, illustrated by stereopticon, "The Prevalence and Geographic Distribution of Hookworm Disease (Uncinariasis) in the United States." He gave a summary of the investigations that have been made and described the different species of the worm.

Having discovered the *Uncinaria Americana*, which differs somewhat in structure from uncinaria in Europe and Asia, Dr. Stiles undertook to determine the geographical distribution of this disease in this country, and accordingly undertook a trip through the southern states. He visited penal institutions, camps, mines, farms, orphan asylums in North Carolina, Virginia, Georgia and Florida, with the result that he was able to satisfactorily demonstrate that such a disease as *Uncinariasis Americana* occurred and could prove the infection by finding the parasite in the stool. The disease produces an anemia, and anemia is usually found in sand areas in the south, due to this parasite. Uncinariasis stands fourth among the prevalent diseases of the south. If the anemia occurs in a clay soil it is due to malaria and where you find a combination of the sand and clay soils you may find both the above-named diseases.

He spoke of the cotton mills of the south as recruiting labor from the farms of the sand areas, so the anemic condition and lack of development of these cotton workers is due not so much to working in the mills as due to a stunted growth due to uncinariasis or malaria before reaching the mills. One-half of the anemias of the south are due to uncinariasis. As to the reason of finding this disease in a sand rather than a clay soil, the feces are deposited in the sand, the embryos are thus deposited, and carried, and secondly, the embryo requires oxygen for its development and gets the oxygen in the sand rather than the clay soil. The hook-worm is known to have lived six years in the intestinal canal, and may live 60 days or longer outside of the body.

Dr. Stiles gave the symptoms of a typical case, and stated that there are all sorts of gradations of the disease. He emphasized the importance of a macroscopic and microscopic examination of feces. In uncinariasis with an ordinary objective, the hook-worm is found in intestinal contents, if in the egg-laying stage the eggs are found. It is not necessary to have much of the feces to make the diagnosis, and either the parasite or eggs are easily found without staining, simply by placing feces between the slide and coverglass. If no eggs or worms are found after examining a dozen specimens it is quite safe to say that uncinariasis does not exist. If by crushing some of the feces on blotting paper a reddish bloody color results 8 out of 10 cases suspected will prove to be uncinariasis.

There is anemia, which may taken on a pernicious form, also eosinophilia. The complexion is waxy white to sallow. In some cases the skin has a yellow tan, and looks not unlike parchment. The mucosa has a marble-white appearance; there are cervical pulsations. The pulse varies from 80 to 132, the average being 120. In some cases there is no temperature, in others the temperature is increased, and it may reach 100. There is a potbelly. Many of the patients look to be pregnant, while the arms and legs are emaciated. The appetite is abnormal; some chew coffee, pickles; some suck lemon, eat salt, sand clay, wood, rags, and one patient ate live mice. There may be constipation or diarrhea. The stools are red or brown, probably due to slight ecchymoses and hemorrhages of the intestinal mucosa.

A symptom noted is that when a patient stares the pupils dilate, and the eye assumes a cadaveric stare, like extreme alcoholic intoxication.

The people are stunted in growth physically and mentally. The penis is small; there is no pubic hair in the male. In females the vulva is small, the sexual organs undeveloped and menstruation is scant.

There may be headache, vertigo, or other nervous manifestations. The disease appears more severe in blondes than brunettes, and also more severe among whites than negroes. Among married women there is a tendency to miscarriages, and it is uncertain whether this is due to the uncinariasis or from the use of large doses of quinin, taken for chronic malaria, with which this condition is universally confounded among southern physicians.

Patients feel better in winter than during the summer months because the eggs and embryos are killed by frost and no new infection can therefore take place.

The treatment consists in thymol, 30 grs. at 8 o'clock a. m., at 10 a. m. another 30 grains, to be followed at noon by salts. It is necessary to prepare the patient by a laxative before using the thymol. It may be required to repeat this treatment from ten to twenty times, and the stools should always be examined.

Dr. Stiles warned against the use of alcoholic solutions of thymol, for it may induce fatal convulsions. This has been proved experimentally in dogs so that thymol is used in the powdered form.

This is a preventable disease. It exists in such localities where little attention is given to the proper disposal of sewage so that a proper disposition of fecal matter is a prophylactic against the spread of the disease. The privy vaults should be boxed and the people must be taught cleanliness, especially the Talmudic dictum of washing the hands before eating.

DISCUSSION.

In answer to a question of Dr. Allen A. Jones as to the value of blood examinations in this condition, the writer stated that

you have the picture of severe anemia. The erythrocytes may be reduced to 800,000, and there is eosinophilia, but he does not depend on blood for diagnosis, comparing this mode of procedure to going from Buffalo to New York by way of San Francisco. The examination of the stool is the method of diagnosis.

DR. UILMAN asked whether or not there were hemorrhages noted. The writers stated that there are slight oozings from the intestinal mucosa, but that he had never noted severe hemorrhages.

AMERICAN PUBLIC HEALTH ASSOCIATION.

Thirtieth Annual Meeting, held in New Orleans, Dec. 8 to 12, 1902.

President, Dr. Henry D. Holton, Brattleboro, Vt., in the Chair.

(Continued from Vol. xxxix, p. 1611.)

Sanitary Measures Proposed to the Mexican Railway Companies.

DR. EDUARDO LICEAGA, president of the Superior Board of Health of Mexico, read a paper on this subject. The measures urged were:

1. To increase the number of cuspidors, and furnish them with disinfecting solutions capable of destroying the tubercle bacilli.
2. Place in conspicuous places placards containing the following: "Please spit exclusively in the spittoons, as otherwise the germs of infectious diseases, especially those of tuberculosis, will be carried into the air."
3. Until the paddings of the cars are changed for other and more convenient drapery, a wise plan would be to disinfect the car, every time it is unoccupied, with a solution of formaldehyd, which would not alter the condition of the cloth or its color.
4. Disinfect all sheets and pillow cases before sending them to the laundry.
5. Also disinfect the tapestries and couches.
6. Keep the car as clean as possible, especially the closets and urinals.

The railroad companies in Mexico considered the above suggestions practical and promised to enforce them.

Co-operation Essential to Progress in Vital Statistics.

DR. CRESSY L. WILBUR of Michigan presented a paper in which he said that for the first time there is an opportunity for continued systematic co-operation between the permanently-organized department of the National Government and the various state and municipal systems of registration to the end that accurate and uniform statistics of mortality may be obtained for the United States and made available for the use of all public health offices.

Vital Statistics: A Plea for Actuarial Administration and Control of the Great Resources of Preventive Medicine.

DR. JOHN S. FULTON, Baltimore, said the Federal census should:

1. Be, at the approach of another census year, better than ever prepared to rapidly and accurately count the people, making notes of all the data needed for statistical purposes.
2. It should make such *ad interim* studies of the births and deaths occurring in non-registration areas as would serve for the better correction of the enumerators' returns for the census year.
3. It should commit all vital returns to the hands of a trained medical statistician who understands the moods and tenses of vital mathematics.

Local registration should cover:

(*a*) Records of deaths made at the time and place of their occurrence, by the most competent persons acquainted with the facts, including a medical certification of the cause of death, the making and filing of such a record being, in every instance, an indispensable preliminary to the disposal of the dead body.

(*b*) Records of birth, secured by the payment of fees, by every appeal to private interest and public necessity, including, if possible, conditioning of certain privileges of citizenship on recorded evidence of attained age.

(*c*) Records of marriage and divorce, with all such items of information as had statistical importance.

(*d*) Records of sickness, including all cases those infectious diseases which fell within the provisions of the notification laws, all cases of sickness which came under study in the public health laboratories, all sickness which was relieved at public cost, and all sickness falling under the observation of inspectors of schools, tenements and factories.

The data of vital statistics should be systematically utilized, not only for the broader purposes which had grown into common use, but for the minuter inquiries to which such records in large numbers and of great variety were adapted.

Transmission of Disease.

DR. LOUIS E. RUIZ, Mexico, presented a paper on the periods in which contagious diseases can be transmitted and also of the periods in which sick persons are dangerous to healthy persons near them.

DR. JOSE P. GAYON, Mexico, spoke of the transmission of pathogenic fungi by flies and mosquitoes.

DR. J. E. MONJARAS, Mexico, discussed the principal causes of infectious diseases and the chief means of guarding against them.

At the evening session of the first day, addresses of welcome were delivered by the Mayor of New Orleans, Paul Capdevielle, on behalf of the city, and by Hon. Jared Y. Sanders, speaker of the House of Representatives, on behalf of the state. These addresses were responded to by President Holton.

Presidential Address.

PRESIDENT HENRY D. HOLTON then delivered his address, reviewing the status of sanitation in the United States, saying the most wonderful progress had been made along all sanitary lines.

The association had been striving for many years for the establishment of a public health service, and the medical profession was to be congratulated that at last their efforts had been crowned with success. While all that was desired had not been granted, yet a substantial, and, in many ways, a satisfactory organization had been effected.

Report of Committee on Public Health Legislation.

DR. U. O. B. WINGATE, Milwaukee, Wis., presented this report, which showed the work done toward the formation of the Public Health and Marine-Hospital Service. It was hoped that this measure provides a foundation on which may be built up a National health service, such as the intelligence of the people and the age in which we are living demand.

Experiments in Disinfection with Formaldehyd Gas.

DR. M. P. RAVENEL, Philadelphia, read an exhaustive paper in which he detailed his experimental work with this gas. He drew the following conclusions:

1. Formaldehyd is justly entitled to the high position which has been given to it as a disinfectant.
2. Special apparatus, while useful and convenient, is not absolutely necessary for the successful application of the gas.
3. The germicidal power of formaldehyd gas is dependent on certain factors which, as yet, are imperfectly understood. Other things being equal, moisture and temperature are the most important of these factors.
4. In practice every operation should be controlled by cultural experiment, and no room which has been exposed to infection should be considered as disinfected unless control cultures exposed in various parts of said room are shown to have been destroyed.

Report of Committee on Disinfection and Disinfectants.

DR. HIBERT W. HILL, Boston, said that a careful examination of articles published in America and Europe had failed to reveal the discovery of any new process of disinfection of great practical value during the last year. As to room disinfection, formaldehyd still holds the first place. Gaseous disinfection, he said, as the great panacea for preventing the spread of contagion, has been much discredited by recent experiments, but the committee were strongly of the opinion that, when properly carried out, it was an important and effective aid in public health work, and would continue to be, and that formaldehyd was by far the best agent to use in carrying it out.

In using formaldehyd two things should be provided for: A sufficiency of water in the air of the space to be disinfected and a very rapid disengagement of the gas. Most forms of apparatus failed in one or the other of those points. The work of Robinson and Hill, members of this committee, clearly showed that not only did efficiency depend on them, but by properly observing them much time and material could be saved. The disinfection of the future must be simple, short and sharp.

Report of the Committee on National Leper Homes.

DR. HENRY M. BRACKEN, St. Paul, Minn., chairman, said that of all the countries represented in the association, the United States was the only one that had made no provision for its lepers. With the present knowledge of leprosy, and the methods employed in care of lepers, the committee advised that the resolution of last year be reaffirmed, favoring the establishment of national leprosaria, which might serve not only as a refuge for lepers, but also as a home and hospital, making their

lives tolerable as far as possible, furnishing employment to those who were able to work, and giving skilled medical care to all cases, with the intent of possibly curing some, and making the road to death less wearisome and painful to others.

Dangers to the Public Health from Illuminating and Fuel Gas.

DR. SAMUEL H. DURGIN, Boston, chairman, reported the investigations of the committee appointed on this subject. They found that the common condition of gas pipes and fixtures was very poor, the moderate small leaks very numerous, and that a moderate increase of pressure in the fixtures above the normal produced leakage in 89 per cent. of all the houses examined. It was also shown that the number of fatalities from illuminating gas was not only large, but was increasing from year to year.

In order to ascertain to what extent the medical profession in Boston had recognized cases of acute and chronic poisoning by illuminating gas, he sent out letters to 2200 physicians, asking for their personal experience in such cases. He received replies from 460 physicians; 246 of them reported no experience; the other 214 reported 1025 cases of acute poisoning; 374 of these resulted fatally; 288 were found dead, and 86 lived from one hour to twelve months; 623 made complete recovery in periods varying from a few hours to three years; 28 made partial recovery, while under observation, of from three weeks to twenty-one months.

Annual Report on Yellow Fever in Mexico.

DR. EDUARDO LICEAGA, Mexico, presented statistics of the spread of the disease along the Mexican coast. The recent epidemic in Vera Cruz developed 877 cases, being the most severe in the country. His report showed that 873 cases were on the Gulf coast, while only 27 cases had been reported on the Pacific Ocean coast. The death rate was low, and had been held down by the successful management of the disease.

DR. NARCISCO DEL RIO, Mexico, related with particularity the history of the spread of the disease in Orizaba, Mex.

Yellow Fever Prophylaxis.

DR. JOHN W. ROSS, U. S. A., gave at length his reasons for believing that the only way in nature for yellow fever to be contracted by man was from the mosquito. He recommended the following measures:

1. To prevent those insects from stinging yellow fever patients.
2. To destroy as far as possible the mosquitoes which have been infected.
3. To consider any place unsafe so long as the last mosquitoes which have stung yellow fever patients may be alive in it.

He stated that the clear-cut, scientific observations and classical contributions of Surgeon H. R. Carter of the United States Marine-Hospital Service, showing the interval (about two weeks) which occurred in houses between the first (infecting) case and the first group of cases, secondarily infected, impossible to explain by the theory of fomites, were now readily understood in the light of present knowledge of the elaboration of the yellow fever poison in the body of the mosquito, that process requiring not less than twelve days.

The Method of Transmission of Yellow Fever from Man to Man.

DR. WILLIAM C. GORGAS, U. S. Army, contributed a paper with this title, giving practically the same views that have been published in previous papers on this subject by him.

DR. MANUEL S. IGLESIAS, Mexico, discussed the disinfection of railroad cars as a precautionary measure against the propagation of yellow fever by mosquitoes.

PROF. GEO. E. BEYER, New Orleans, related his investigations regarding yellow fever in Vera Cruz.

DR. EDMOND SOUCHON, New Orleans, did not antagonize the theory of the transmission of yellow fever by mosquitoes, but he did not believe that we were prepared to say that the mosquito was the only mode of transmission of the disease. After a close and careful study of the question, he had reason to believe that there was some other means of transmission. What it was he could not say. It might be fomites, or something we know nothing about.

DR. HAMILTON P. JONES, New Orleans, who was in charge of the Beauregard Yellow Fever Hospital in this city in 1896, said that, despite the fact that three hundred people were exposed to mosquitoes as transmitters of the disease, as well as to fomites, not one of them had been stricken, and he was still in the dark as to the doctrine of transmission of the disease.

DR. JOHN GUITERAS, Havana, explained the prophylactic measures carried out in Havana.

DR. E. R. CARTER of the Marine-Hospital Service said that if the disease was conveyed to an animal host, it was conveyed there by a parasite. He said the conveyance of the disease might occur in two ways by fomites: First, directly to the person, and, second, through an infected atmosphere.

DR. QUITMAN KOHNKE, New Orleans, after mentioning the fact that the board of health was doing all in its power to guard against the disease, said that still more strenuous efforts should be made to keep it from coming to New Orleans from infected ports. If the disease was conveyed by fomites as well as by mosquitoes, it was logical to conclude that there was a greater danger than if it was conveyed alone by the *Stegomyia fasciata*.

Proceedings of the Section on Bacteriology and Chemistry.

The Occurrence of Tubercle Bacilli of Increased Virulence in Man.

DR. M. P. RAVENEL, Philadelphia, stated that it is rare to find tubercle bacilli in man which have a high degree of virulence for experimental animals, if one judge by the published reports, and it is still more rare to find cultures which are highly pathogenic for cattle. So marked was the difference in pathogenic power of cultures isolated from man on the one hand, and from cattle on the other, that a division into races had been proposed depending on this feature; and Koch held that inoculation of a given culture into cattle would surely show whether it was of human or bovine origin. Believing that bovine tuberculosis is a fertile cause of the disease in milk-fed children, he had for some time past taken every opportunity possible of selecting cultures of tubercle bacilli from the mesenteric glands of those who had died of a tuberculosis which was not clearly of respiratory origin. This had led to the discovery of two cultures, one of which was as virulent for all animals on which it had been tested as cultures obtained from cattle usually were; and the other, while not nearly so virulent, was still much in advance of the usual human culture.

DR. F. P. DENNY, Brookline, Mass., read a paper on the morphology of *Bacillus diphtheriæ*, *Bacillus pseudo-diphtheriæ*, and *Bacillus xerosis*, based on the study of serial preparations made at intervals from the same cultures.

The Use of Immune Serum in the Separation of Typhoid and Colon Bacilli.

DR. ADOLPH GEHRMANN, Chicago, read this paper. The difficulty in the separation of these species was due to the constant tendency of *Bacillus coli* to overgrow *Bacillus typhosus*. The search for specific retaining agents had not resulted in entire success. If an immune serum, active for one or the other species could be used to restrain the growth of one, without disturbing the growth of the other, it would be an ideal method of procedure. He related previous experiments along this line. The serum of rabbits immunized against *Bacillus coli* could be used for this purpose and gave results that were positive by artificial mixtures of the two species. The method could be improved by using the blood of immune animals direct and by rapid cultivation in the incubator. For practical purposes this method was not as yet certain and the establishment of a control was difficult. On material containing other species the restraining effect of carbolic acid did not disturb the purpose of the blood that was used. Some rather indefinite results on the isolation of typhoid from water had been reported.

An Examination of the Value of Certain Antiseptics Used for the Preservation of Antitoxin and Other Immune Serums.

DR. JOSEPH MCFARLAND, Philadelphia, said this investigation had for its object the determination of the antiseptic and bactericidal values of chloretone, formaldehyd, chloroform, trieresol and carbolic acid. It had long been believed that the addition of one-half per cent. of carbolic acid and 0.4 per cent.

of tricresol, and 0.1 per cent. of formaldehyd would satisfactorily prevent the growth of micro-organisms in the serums so prepared. As some of these reagents threw down a precipitate, the question arose whether the reagent itself was destroyed and too little remained to properly preserve the serum.

The research was conducted by preparing the serums with the proper proportions of the germicides, then adding known numbers of bacteria and determining their diminution or increase. The results showed that, other things being equal, formaldehyd was preferable to phenol, but objectionable because it did not kill molds. Phenol was better than tricresol, and the recommendation was made that hereafter tricresol be given up as a preservative of the serum.

Formaldehyd.

DR. H. W. HILL, Boston, read this paper. His conclusions were that humidity was an important factor in formaldehyd disinfection. An amount of gas which failed to kill in six hours at 42 per cent. humidity, killed in twenty to forty minutes at 100 per cent. humidity. Considering the unavoidable leaks and absorption of gas by walls, etc., found in practice, practical disinfection required a rapid discharge of gas and high humidity. The best of the generators tested ran not more than 15 c.c. per minute, and the condensed effluent yielded in the first ten minutes only about a 30 per cent. solution, hence generation by boiling in the ordinary way was too slow. Spraying was somewhat objectionable from the wetting down of the contents of the room. Atomization by steam current under 15 pounds pressure yielded from six to eight times as rapid a flow of full strength, with no polymerizing, and produced a high humidity.

The Diminishing Importance of Public Water Supplies and the Consequent Significance of Other Factors in the Causation of Typhoid Fever.

PROF. W. T. SEDGWICK, and MR. C. E. A. WINSLOW, Boston, undertook to show:

1. That in the State of Massachusetts and in many of the larger cities of the United States the public water supplies are now unimportant as vehicles of typhoid fever.
2. That in cities having pure water supplies the annual curve of typhoid fever mortality closely follows that of annual temperature.
3. That in urban communities supplied with pure water there still remains a typhoid fever tax of from 15 to 25 deaths per 100,000 population.
4. That this tax is due not to any peculiar conditions of soil, locality or climate (endemic factors), but to incomplete disinfection of typhoid excreta with subsequent infection of various articles of food and drink. These factors, when acting on a few or many persons at one time, may cause obvious epidemics, sometimes large, though generally small; but more often the infection in moving from one point to another follows different and obscure routes for different victims, and hence may be described as prosodemic.
5. That the only remedies for such prosodemic typhoid are absolutely thorough and universal cleanliness and disinfection of excreta.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Creosote and Guaiacol in Pneumonia.

A correspondent asks for the therapeutic uses of carbonate of creosote, particularly in pneumonia. Creosote and its derivatives have been the subject of much discussion, some reporting them as specific in pneumonia and some considering that they have no effect. They are discussed, both pro and con, in the "Symposium on Pneumonia" in THE JOURNAL, Nov. 15 and 22, 1902. Our correspondent is further referred to the U. S. Dispensatory for a description of the drug in question. The therapeutic uses include tuberculosis, chronic bronchitis, enteritis, ulcerations, intestinal indigestion and various other derangements of the alimentary canal. The carbonate is said to be less irritating and less toxic than creosote. The former is not soluble in water or glycerin, but is soluble in 4 or 5 parts of olive oil or sweet oil, or may be administered in capsule or in the form of an emulsion. It is decomposed in the intestine and is separated into creosote and carbonic acid. It is said to improve the appetite rather than to disturb it. The dose is from 3 to 15 minims, but should not exceed one dram in the twenty-four hours.

Dr. L. Weber of New York and Dr. J. L. Van Zandt of Texas have given very favorable reports of a large number of cases of pneumonia in which creosote carbonate was used. The latter says it may be urged that pneumonia being a self-limited disease, even bad cases will recover; but, on the other hand, good and uncomplicated cases die in spite of the best of care and the so-called symptomatic treatment, because the system does not furnish a sufficiency of serum antitoxins to end the pneumonic process. Unfortunately it can not be told in any case of pneumonia whether Nature will be able to cure the patient. Weber believes that this remedy is able to supply Nature's deficiency, working, as it does, in a very similar way to the antitoxins furnished by the system.

Dr. E. Fletcher Ingals favors the use of guaiacol applied externally rather than the use of the creosote preparations by internal medication. He states that it is rapidly absorbed, and consequently the prompt and beneficial effects are produced without any disturbance to the digestive tract. He advises its application externally in doses of 20 or 30 minims whenever the temperature reaches 101.5 F. and repeated every three or four hours if the temperature indicates it. Different areas should be chosen at each application.

Aborting a Venereal Bubo.

The following, according to an article in *Merck's Archives*, has been used successfully in aborting venereal buboes:

℞.	Ung. hydrarg.		
	Ung. belladonnæ		
	Ichthyol		
	Lanolini, āā 3ii	8	

M. Ft. unguentum. Sig.: Apply locally. If the bubo is seen early, no heat or redness being present, a piece of surgical lint spread with ointment is applied to the swollen gland; over this a piece of oiled silk of the same size. A piece of cotton is then applied, and firm, continuous pressure applied by means of a bandage. This treatment is applied every other day until, in cases in which it acts successfully, entire resolution takes place, usually in about two weeks. Or the following ointment may be used:

℞.	Emplas. hydrargyri		
	Emplas. plumbi, āā 3iv	16	
	Olei terebinthinæ 3i	4	
	Ichthyol 3ii	8	

M. Sig.: Applied locally.

The following is recommended as an injection to prevent suppuration:

℞.	Hydrarg. benzoatis .....gr. v		30
	Sodii chloridi .....gr. iiss		15
	Aquæ destil. .....ʒi	30	

M. Sig.: As an injection.

Eucalyptus in Diabetes.

Faulds, in *Glasgow Med. Jour.*, has employed with success an infusion of eucalyptus in the treatment of diabetes as follows:

℞.	Eucalyptus flores (dried) .....ʒiv	16	
	Aquæ .....ʒvi	180	

M. Fiat infusum. Sig.: One such draught to be taken twice daily. He states that he obtained good results in fifteen out of sixteen cases. In one case, a girl of 18, in which there were sixty grains of sugar to the ounce of urine passed, after four days' treatment only one grain to the ounce was passed, and on the sixth day none. He, however, thinks it of service only in those cases due to gout, overindulgence in food, or cold. It does not seem to be of service in those cases dependent on vasomotor disturbance affecting the blood supply to the hepatic cells as no improvement was shown in those cases. Eucalyptus oil or eucalyptol will not produce the same results as the infusion.

Massage in Nephritis.

Ekgren, in an abstract in *Med. Rev.*, states that active exercise increases the percentage of albumin in nephritis, and is,

therefore, contra-indicated. Demonstrations on cases of both the interstitial and parenchymatous forms of nephritis showed that passive movement and general massage were equally harmful, as they were followed by considerable increase in the quantity of albumin. The practice of treating renal anasarca by massage, according to the author, should be abandoned or applied only in exceptional cases.

Psoriasis.

Sherwell, in *Jour. of Cutaneous and Genito-Urinary Diseases*, recommends the following outline of treatment of psoriasis:

℞.	Quininæ sulph.	gr. xxx	2
	Mag. sulph.	ʒi	30
	Acidi sulph. dil.	ʒiii	12
	Tinct. nucis vom.	ʒss	2
	Vini colchici	ʒiiiss	14
	Glycerini	ʒiss	45
	Aquæ	ʒii	60

M. Sig.: One dessertspoonful night and morning in a wineglassful of water, half a glass of water to be drunk directly after.

The following to be applied locally:

℞.	Liq. carbonis detergentis	ʒiii	12
	Acidi salicylici	gr. xv-xxx	1-2
	Ung. aq. rosæ	ʒxi	44

M. Sig.: Apply locally night and morning.

Fissure of the Hands.

The following is recommended by Steffen in *Bul. Gen. de Ther.* as an ointment in the treatment of fissures of the hands:

℞.	Menthol	gr. xx	1 30
	Salol		
	Olei olivæ, āā	ʒss	2
	Lanolini	ʒii	60

M. To be applied twice a day.

J. Nevins Hyde employs the following for cracked and chapped hands:

℞.	Tinct. benzoini	ʒiss	45
	Tinct. tolutani	m. lxxv	5
	Glycerini	ʒss	15
	Spts. vini rect.	ʒiii	90
	Aq. rosæ q. s. ad	ʒvi	180

M. Sig.: Wash the hands thoroughly in warm water and apply locally night and morning.

Alopecia.

The following formulæ are credited to Balzer in *Amer. Med.*, to be employed in the treatment of alopecia areata in preference to epilation to stop the progress of the disease:

℞.	Hydrarg. biehlor.	gr. iii	20
	Acidi acetici	m. xv	1
	Alcoholis, 90 per cent.	ʒiii	90
	Spts. etheris		
	Spts. lavendulæ, āā	ʒiv	120

M. Sig.: Cut the hair. Wash the scalp once daily with the foregoing solution.

To re-establish the function of the hair follicles and the atrophied papillæ the following lotions should be used:

℞.	Res. ammoniaci	gr. lxxv	5
	Spts. terebinthinæ	ʒvi	24
	Camphorated alcohol	ʒiv	120

M. Sig.: Apply locally; or:

℞.	Acidi acetici	gtt. xv-lxxv	1-5
	Chloral hydratis	gr. lxxv	5
	Spts. etheris	ʒvi	24

M. Sig.: Apply locally; or:

℞.	Acidi lactici	ʒii	8
	Alcoholis (90 per cent.)	ʒi	30

M. Sig.: To be applied by means of a tampon of absorbent cotton and friction employed until the skin is reddened. If too much irritation is produced the treatment should be withheld for a time.

Diphtheria.

Dr. N. Novikov, according to *Amer. Med.*, states that the use of hydrogen dioxid, to the exclusion of all other medication, in the treatment of diphtheria, gives results equally as encouraging as serumtherapy. The false membrane is detached more slowly than by the serum, but the depressant action of the diphtheritic toxin is neutralized to a great extent by the hydrogen dioxid which favors oxidation. The author instructs the patient to use two or three tablespoonfuls of a 2 or 3 per cent. solution to a glass of water as a gargle night and morning. In children too young to gargle he prescribes the peroxid to be taken internally, as follows:

℞.	Sol. hydroglini peroxid	ʒi-ii	4-8
	Syr. simplicis	ʒiv	16
	Aq. destil.	ʒiii	90

M. Sig.: One teaspoonful to a dessertspoonful every hour or two.

In order to hasten the detachment of false membrane, the throat may be painted with a 2 or 3 per cent. solution three times a day.

Hydrogen Peroxid in Poisoning from Coal Gas.

Hydrogen peroxid is recommended by *Merck's Archives* in the treatment of coal gas poisoning, administered per rectum and per os. It is given in doses of two ounces (60.) full strength, per rectum; per os one ounce (30.). This dose may be frequently repeated. The success of the treatment of course depends on the absorption of the oxygen from the solution by the blood current. A piece of ice inserted into the rectum is a great adjuvant and has a remarkable effect in restoring consciousness.

Chronic Bright's Disease.

The following combination is recommended by Semmola as a drink in chronic Bright's disease:

℞.	Sodii chloridi	ʒiss	6
	Sodii phos.	ʒss	2
	Sodii iodidi	gr. xv	1
	Aquæ puræ	ʒxxxvi	1080

M. Sig.: Use pure as a drink or mixed with milk.

Medicolegal.

Registration of Physicians in Missouri.—The Court of Appeals at Kansas City, Mo., says, in the case of State vs. Morgan, that the laws of 1874 required all practicing physicians to register, and when registered they were thereafter qualified to practice. No law since that enactment has required them to again register. In regulating the practice of medicine, in 1877, the legislature exempted those who were then authorized to practice by virtue of any existing law. Laws 1877, page 343, section 1. In a subsequent regulation, in 1883, the provisions then enacted were made non-applicable to physicians who had been practicing five years. Laws 1883, page 116, section 11. The act of 1883 continued in force down to 1901, when a new regulation was made by the legislature. But it was therein provided that it should only apply to "any person not now a registered physician." Laws 1901, page 207, section 1. The competency of a physician to practice medicine under the act of 1874 has, therefore, not been interfered with by subsequent regulations.

Care Required to Prevent Aggravation of Injury.—The Court of Civil Appeals of Texas says, in Texas & Pacific Railway Company vs. McKenzie, a personal injury case brought by the latter party, that, to prevent aggravation of the injury, the party injured is only required to use such care and caution as an ordinarily prudent person would use under similar circumstances. The aggravation of a wound by unskilful treatment would not of itself prevent the recovery of damages by reason of such aggravations, unless the injured person failed to use ordinary care to prevent such aggravation. When a personal injury flows from the negligent act of another, that other is responsible for the damages resulting, and all that the law demands of the injured party is to use ordinary care to avert further injury. Here, if the company negligently caused the injury, then it was responsible for the damages that proximately resulted therefrom. Whether it was responsible for the aggravation, if any, caused by a failure of prompt attention or unskilled treatment, depended on the care used by the injured party to have the injury properly treated.

Allows But One Physical Examination.—The second appellate division of the Supreme Court of New York says, in Whitaker vs. Staten Island Midland Railroad Company, that it is true that the statute of that state which provides that on application the physical examination of a party seeking to recover for personal injuries may be ordered contemplates the appointment of a physician by the court, but where the party sued has waived this right and a physician of his own nomination has been permitted to examine the other party, and has testified without objection, he may not properly discard such testimony, and ask the court to permit an entirely new examination. The provisions of the Code of Civil Procedure in reference to examinations before trial were intended as an extension of the privileges of parties sued in actions for personal injuries, but the rule is well settled that a party may waive a rule of law, or a statute, or even a constitutional provision enacted for his benefit or protection, where it is exclusively a matter of private right, and no considerations of public morals are involved, and, having done so, he can not subsequently invoke its protection. So the court is of the opinion that the railroad company sued, having once waived the right to an examination by a physician appointed under the order of the court, could not take advantage of the provisions of Section 873 of the Code providing for examinations as above stated. The general purpose of the enactment, it says, was to change a rule of the common law, and it ought not to be extended beyond the clearly expressed intention of the legislature, which, while not expressly limiting the examination to a single occasion, makes no provision for more than one examination, and this is before trial. Again, it says that it appeared that the principal claim of the party suing was that the injuries had resulted in traumatic neurasthenia; and says that this was a matter which might be determined quite as accurately from the testimony which must be brought out on the part of the party suing and her witnesses under cross-examination as by any mere physical examination four or five years after the accident. The company had had all of the advantages of the provisions of Section 873, and it had, by accepting a physical examination under the stipulation of the party suing, waived any right to have another physician appointed by the court for the same purpose.

1.—See THE JOURNAL, xxxix, p. 1411.

2. **Laryngectomy.**—In the earlier part of his article Hartley described total laryngectomy, and here he remarks that a complete unilateral laryngectomy is done in the same manner except that the operative work is confined to one side. In the less extensive cases it may be done subperichondrally. In all cases a tracheotomy is made at the second or third rings, and the cricoid cartilage is saved, if possible. The wound remaining is closed as far as possible by the mucous membrane of the pharynx and the remainder is packed as in resections. In all other details the measures adopted in the resections are applied to the partial laryngectomy. For three days the patient is kept in bed with the foot raised without a pillow, and nourishment given by the rectum every sixth hour, and rectal irrigations with salt solution every third hour. On the third day an attempt to swallow is made—at first of water only, taken in the mouth in the exaggerated Trendelenburg posture, that is, swallowing "up hill." If the wound is not closed some leakage will occur, but this can be overcome by compressing the sides of the opening with the fingers. If this can not be done, or if the wound could not be closed at the time of the operation, a catheter should be used, best inserted through the nose. It is preferable to avoid the use of the catheter, however. He thinks that unless lymphatic involvement contraindicates operation, unilateral or bilateral removal is justifiable. He does not speak with favor of the establishment of an artificial larynx as there is a remarkable adaptation of organs to replace the function of the lost ones in these cases. He reports five cases of these operations.

3. **Gynecologic Massage.**—Talmey reviews the objections and advantages of gynecologic massage. He thinks it is indicated in every case in which pressure on any part of the internal genitals causes sudden and perhaps persistent pain. It is indicated in all cases where it is desired to help Nature improve the circulation by absorption of the products of exudation and increase the tonicity of the tissues, and it will do away with the necessity of many hysterectomies, dilatations, curettements, and oöphorectomies. The dangerous operations for retroflexion will also be avoided, and the ovaries that otherwise might have been sacrificed be saved. He gives details which we can not here reproduce.

4. **Alexander's Operation.**—Broun prefers Alexander's operation in suitable conditions for the following reasons:

1. The relief it affords patients from symptoms on account of which they seek counsel.
2. The danger is *nil*, and the operation of far less gravity than other surgical means in use for the relief of the same symptoms.
3. The anatomical result obtained is all that can be desired, and is effected without the establishment of new pathological adhesions, the intentional formation of which form the basis of all vaginal fixations or ventral suspensions.
4. That the much-heralded danger of inguinal hernia as following this operation is greatly exaggerated, provided the operation is properly done, without laceration of the surrounding tissues in a long continued search for the ligament. If such laceration has taken place, hernia is impossible, if the operator (recognizing the possibility of such) continues his incision to the internal ring and does a Bassini operation, which does not prevent his shortening the ligaments at the same time.

6. **Irrigation Treatment of Gonorrhea.**—Valentine notices the various causes of failure of this method. Among them the possible idiosyncrasy of the physician. Not every doctor is qualified to treat genito-urinary cases, but he does not consider this as against him. He admits he has himself an abhorrence for obstetrics and gynecology and a great dread of treating children's diseases, and would consider himself unfit for such work. He notes the time required as an objection, but that is not a valid one. Also the need of employing irrigating solutions to suit the case; permanganate is not a panacea for all. The patient may be rebellious or unable to carry out the treatment. He mentions a method and apparatus for autoirrigation, which has been described elsewhere. Among the congenital defects which may interfere is a very tight preputial orifice, which may require circumcision or incision, or narrow meatus, intraurethral abnormalities, epispadias and hypospadias. Among the acquired complications are balanitis and balanoposthitis, chancre, chancroid, cicatrices, condylomas, herpes progenitalis, infiltrations, paraphimosis, phimosis, prostatitis, stricture, etc. Phosphaturia and oxyluria may exist, which must be overcome before an effect from irrigation can be expected. These, he thinks, are the principal causes for the failures that occur in the irrigation treatment of gonorrhea.

7. **Infant Feeding.**—The first point in infant feeding is to get a careful personal history of the case from birth, the second, to get a good clean milk, the third point is to get the proportion of fat according to the percentage of fat, proteids, and sugar in the different ingredients; that is, to think in percentages. Hand began by using Meigs' mixture, equal parts of milk, cream, barley water and limewater. He shows how by simple calculation, the sugar, fat and proteid can be modified

from this, by reducing the cream, milk, etc., or adding sugar as required. If the child does not show a weekly gain in weight we should see if the feeding is being carried out as directed. He believes in the use of barley water as a diluent, except in cases where constipation exists, and then oatmeal water is to be preferred. Cane sugar, a pinch of salt, and a tablespoonful of limewater should be added to each feeding. With patients three months old and upward he aims to have the proteid at least 1.75 per cent., and increases it as rapidly as the child can digest it. Infants under three months require careful handling, both as regards proteids and fat, and to tone up the digestion he uses a little sodium bicarbonate in compound infusion of gentian before each meal in some of these cases.

9. **Obesity and Improcreance.**—Stern notes the increase of obesity with decline of sex function, and reviews the causative factors. The abnormal conditions called out by the loss of the sexual stimulus and non-performance of sexual functions, preventing the expenditure of body material, may tend to obesity. In the female organism the possible participation of the surplus blood after the menopause in nutrition is also suggested, or the apparently discrepant condition of the diminution of tissue oxidation and decrease of the red blood corpuscles. There is a lessened degree of intensity of vital processes in the castrated, and in the beginning of the menopausal period, and reviewing the possible factors we find that they all depend on diminished intra-organic oxidation. There is little doubt that the sexual glands, particularly the ovaries, have other functions than those so well known to us, and while we know nothing definite about this it is very possible that their loss may cause chronic disturbances of nutrition, of which obesity is one of the most important.

10. **Electrothermic Hemostasis.**—Downes describes and illustrates the forms of the electrothermic angiotribe and details their purposes. By the electrothermic methods of hemostasis there is elimination of all the handling required in the preparation of the ligature and the operation of ligation. Further advantages are the bloodless nature of the operations, and the closing of lymphatic vessels. He has had no secondary hemorrhage in one hundred operations, unless, perhaps, in one or two cases where there has been too little heat and too short an application. The hemostased track that does not bleed immediately on section gives him no concern. He thinks the method is specially applicable to hospitals, and it is of value in oöphorectomy, appendectomy, or occlusion of the small arteries for which he has devised a special type of instruments, for hemorrhoidal operations, etc. He cites two hysterectomies for cancer performed within a month, in neither case of which was any ligation used. In conclusion he calls attention to the following points, which should be borne in mind by those not accustomed to the method:

The pressing surface of the blades must be smeared with sterile oil before each application. The field should be dried and freed from blood and the surrounding tissues protected from the outer surface of the blades. After each removal of the blades from a hemostased track all charred adhering blood must be removed from their surfaces. Too short an application should be avoided. No error is committed if the time is half a minute longer than required. It should be distinctly understood that the term cauterized does not apply to the method of hemostasis by electrically heated pressure instruments. To cauterize is to burn. In this process we cook the compressed ribbon of tissue, a vastly different thing from burning it.

11. **Tuberculin in Diagnosis.**—Madison has employed tuberculin in over five hundred cases, taking the temperature every four hours for three to five days before the first injection. The injection was given at 8 p. m., and for the next twenty-four hours the temperature was taken every two hours. If there was no reaction from the first injection, a second one was given three days later, and after this the temperature taken for three days or longer if desirable. In a short time the routine was adopted of giving a first dose of 4 mg., followed if necessary by 7 mg., as the maximum dose. Koch's original tuberculin was used. A .5 per cent. carbolic acid solution was usually made up so that each c.c. contained 2 mg. of tuberculin. The solution was made up every three to five days and kept in a cool, dark place. A rise of 2 degrees F. during the following twenty-four hours was considered a temperature reaction, and in many cases the reaction was determined wholly by the temperature chart. He reports some eight cases, and he finds that the test has a certain percentage of failures, and reaction may occur in healed cases or cases that are not tuberculous. His conclusions are given as follows:

1. Patients may react to tuberculin and no evidence of tuberculosis be found at autopsy.
2. The six cases following seem to demonstrate that completely healed tuberculosis may react.
3. Cases of proved tuberculosis may not react to the maximum doses.
4. The evidence is not conclusive that other diseases than tuberculosis may react to tuberculin.
5. The margin of error of the tuberculin test is considerable and probably not less than 10 per cent.
6. The maximum dose should be higher than 4 mg., and not more than 10 mg. Small increasing doses are not advisable, as the reaction is not so likely to be distinct on account of the tolerance which may be produced. An initial dose of 3 to 5 mg. followed by the maximum dose is better.
7. The temperature should usually be normal before injections are given. When the temperature is distinctly above normal a negative result is of no value, as these patients will frequently not respond at all, even to large doses.
8. It seems quite certain that the glycerin extract of tuberculin deteriorates, and a fresh bottle should frequently be opened, care being taken to keep it in a cool, dark place. The .5 per cent. carbolic acid solution should be made up on the day it is used if possible. I believe that deterioration of tuberculin is the principal factor in producing delayed reactions.
9. It can not be said that tuberculin injections are entirely without ill effects, but their use among suitable patients is no more dangerous than the use of chloroform and ether for diagnostic purposes and is quite as justifiable as an early diagnosis of tuberculosis is of the greatest importance.
10. About 40 per cent. of all female patients admitted to the hospital react to tuberculin.

17 Some Observations in the Children's Hospitals of London and Paris. Linneus La Fétra.
18 Impressions of the Non-heredity of Acquired Characters. Lewis S. Blackwell.

14. **Scientific Aspect of Modern Medicine.**—Lee reviews the conception of vitality (which he considers has been a hindrance to the progress of medicine), the cell doctrine, the rise of bacteriology, modern surgery, modern germ theory of disease, progress of preventive medicine, serumtherapy, internal secretion, brain surgery, new physical chemistry, medical education, etc. He thinks the future of scientific medicine lies with the university, and that the ideal medical school will be an important department, and on a basis more nearly parallel with that of the non-professional schools of the university at the present time.

15. **Acute Pancreatitis.**—The varieties of pancreatitis with their special features are noted by Woolsey, who remarks that in the three cases here reported there is little to suggest the etiology, except that alcohol in two was an important factor, probably by causing gastroduodenal catarrh. The symptoms in all were much alike. There was sudden onset with more or less collapse, general prostration, severe and cramp-like epigastric pains, not relieved by vomiting, abdominal distension and irregular temperature. There was some abdominal rigidity and tenderness, but no mass could be palpated. In only one of the cases was there obstinate constipation simulating intestinal obstruction, which is not infrequently observed in this disease and may lead to errors of diagnosis. Glucose in the urine was present in Case 3, and helped in the diagnosis; fat in the stools was not observed in any. The diagnosis is always difficult and uncertain on account of the variety of inconstant and contradictory symptoms. In the first one of the cases reported the diagnosis was made only after the operation, and in the second a probable diagnosis was made on account of the recent occurrence within a week of the first case. Case 3 was diagnosed by a group of typical symptoms combined with alcoholic history and glycosuria. It is generally admitted that operation must be avoided in the early stages of collapse. The treatment resolves itself into that of peritonitis commencing in the superior abdominal region, and usually anterior incision, but Robson recommends in addition, or as a substitute if the diagnosis is made, a posterior incision in the left costo-vertebral angle. The prognosis is grave, but varies with the severity and form of the acute inflammation. The hemorrhagic cases are worst, the necrotic

form next, if not fully as bad. In the variety here described he was able to save the patients, though the good results in his three would not apply to a large number of other cases. Recovery without operation is probably impossible, though two cases have been reported after spontaneous evacuation through the bowels. The abdomen was opened and drainage used in his three cases, with recovery.

16. **Rubella Scarlatinosa.**—Curtis and Shaw report an epidemic of about 200 cases, which was described in THE JOURNAL, Aug. 30, 1902, p. 492, as "fourth disease." They point out the differences between these cases and scarlet fever, and consider that this outbreak was rubella, and not at all a distinct disease.

25 Congenital Absence of Pectoral Muscles. Charles V. Burke.

19. **Gonorrhea.**—The increasing evidence of the constitutional character of gonorrheal infection is noticed by Bull, who believes the gonococcus penetrates the general system, both by the blood vessels and the lymphatics. He remarks that instances of sudden loss of sight in patients affected with septic endocarditis which had been attributed to embolism, have been more recently explained by obliteration of the retinal vessels by gonococcal infection. If the aorta and heart can be attacked by the gonococcus, it is natural to conclude that retinal thromboses can be due to the same cause. As regards gonorrheal rheumatism, the facts are not so corroborative of the constitutional character of the disease. The arthritis has not been so definitely proven to be a localized product of general infection, but we have more positive evidence of the dependence on sysmatic iritis and choroiditis and the plastic character is less gonorrhea. It develops more rapidly than the ordinary rheumatic iritis and choroiditis and the plastic character is less pronounced. It is an uncommon complication; though obstinate and subject to frequent relapses it invariably subsides and usually leaves little or no traces behind it. He illustrates his views with five cases reported in detail of iridochoroiditis due to gonorrheal poisoning.

21. **Typhoid Spine.**—Ely details a case which he has had exceptional opportunities to observe. He remarks that there has been little contributed to the pathologic condition since Gibney's first case. It is quite possible that there is the same analogy between typhoid spine and Pott's disease as there is between typhoid pneumonia and tuberculous pneumonia. One tends to the acute course and comparatively rapid recovery, and the other to a more chronic course and breaking down of tissue. He feels certain that it is an osteitis, probably combined with periosteitis. In the case reported it is reasonable to assume inflammation first affecting one region that subsided there, and then attacked adjacent regions of the spine. Neuritis was caused by the inflammation of the bone and of the periosteum, and probably one or more of the spinal articulations were involved. Ely remarks on the bad manners of the Germans in giving little attention to the original authority in regard to the disease. He gives a brief analysis of the symptoms from the cases reported. The prognosis is good. All authorities, except Osler, agree that the treatment is rest—the more complete the better. The recumbent posture is the best, perhaps in a plaster-of-paris bed, with later a spinal brace or plaster-of-paris jacket. Local treatment, like massage, electricity, heat and cold and so on may be of use.

27. **Irritative Bronchitis from Inhalation.**—A number of cases of irritative bronchitis due to chloroform, gas, sulphur gas, formaldehyd, etc., have been recently observed by Hall, and he reports several. In no case, however, was there any autopsy. Fumigators and others are warned to avoid the irritating fumes.

28. **Nasal Polypi.**—The pathology of nasal polypi is held by Solenberger to be due to irritation, usually from necrotic bone. He does not affirm that this is invariably the cause; some polypi may originate in the mucosa and some in the lower layer of the periosteum along the lining membrane of the cavities, but most of the polypi in the cases he reports seemed to grow from bone necrosis.

29. **Localized Posterior Staphylomata in Myopia.**—Seven cases are reported by Chance. Their characteristics are sharply circumscribed areas, depressed beyond the level of the surrounding fundus, as shown by the difference of refraction. The ectasiæ are composed only of sclera, which has a pearly luster, with here and there on the surface thin grayish pigmentations, much resembling those of cases of true coloboma of the choroid, rather than the dense collections seen after colloid atrophy. The disc margins are hazy, the optic disc seems to be tilted toward the ectasis, the central depression and also the vessels as they emerge trent toward it and appear to dip to a deeper level, which they surmount when they approach the opposite side in the nasal vessels. The arteries are thinner in caliber than the veins, while the color of the venous currents is decidedly deeper than that noticed in the vessels distributed in other regions, and the capillaries are more numerous. The temporal vessels run either to the nasal edge of the disc or beyond the margin, and then turn back sharply to be distributed to the temporal portion of the fundus. In the cases of ectasis localized to the inferior border of the disc, a relatively similar anatomic arrangement was noticed. All the eyes have been highly myopic, with scarcely any other defects of structure, and although the macular regions have been unaffected, the corrected visual power is much less than the normal. In each of the instances reported the patient was intelligent and carefully noted the ocular symptoms. He thinks they are instances of true staphylomata of congenital origin and not expressions of the changes taking place during the progress of increasing myopia.

36 The Ups and Downs of a Physician's Life. (Continued.) George J. Monroe.
37 Surgery of the Prostate, Pancreas and Diaphragm. (Continued.) B. Merrill Ricketts.

32. **Sputum Staining.**—The method recommended by Smith requires the following solutions:

Anilin oil gentian violet. IKI solution, iodin 1, potassium iodid 2, water 300. Saturated aqueous solution of eosin. Loeffler's alkaline methylene blue. Alcohol, 95 per cent., 4 parts, ether 6 parts. Ninety-five per cent. alcohol, absolute alcohol, xylol.

The best results are obtained when the stains are fresh. The specimen should be examined as soon after it has been raised as possible, as standing favors the growth of bacteria. No carbolic acid or corrosive sublimate solution should have been added to the specimen.

As thin a cover glass preparation as possible should be made from the sputum, by means of a sterile platinum loop. This is more essential if it is at all bloody, as is so frequently the case in pneumococcus pneumonia. Fix the preparation in the ordinary way, by passing two or three times through the flame. Cover the specimen, thus fixed, with anilin oil gentian violet, holding it well above the flame, and allow it to steam. Avoid burning.

Wash off the excess of anilin oil gentian violet with IKI solution; cover with IKI solution, and allow to steam as before. Decolorize as much as possible with 95 per cent. alcohol. Wash a few seconds in alcohol ether solution. Wash in water. Stain a few seconds in saturated aqueous solution of eosin. Wash off excess of eosin with Loeffler's blue; cover with Loeffler's blue, steaming as before.

Decolorize slightly with 95 per cent. alcohol; wash in absolute alcohol; follow with xylol; mount in Canada balsam, and examine with an oil immersion lens.

The appearance of the stained specimen is given. Leucocytes, lymphocytes, and other cells take the eosin stain, as well as the red blood corpuscles, the nuclei staining with Loeffler's blue. Eosinophiles appear as in stained blood preparations. Gram staining organisms appear black or deep violet, while Gram decolorizing bacteria take the Loeffler's blue stain. Capsules about organisms, when present, are stained by the eosin, as are ciliæ. He advises the first staining of the specimen in the routine examination for tubercle bacilli to be by one of the usual methods, and to note whether the leucocytes contain numerous minute bacilli. If such are present, they may be influenza bacilli. If no tubercle bacilli are found after several cover glasses have been examined, stain another specimen as above described, noting the following points: The number and staining reaction of the organisms present; the abundance or otherwise of the leucocytes, and whether they are phagocytic; the frequency or rarity of the occurrence of blood globules, and the presence of pigment cells, ciliated epithelial cells and eosinophiles. He remarks that the pneumococcus may be found in small numbers. Considerable stress is given to the importance of the influenza bacillus alone and in connection with other organisms. What he wants to emphasize is that further examination of the sputum is necessary than is usually made, and that it is not sufficient simply to examine for tubercle bacilli, but that the influenza bacillus should be looked for in every case of chronic disease of the lung.

33. **Influenza.**—Lord concludes as follows:

1. Infection with influenza bacilli is prevalent apart from an epidemic of influenza. Influenza bacilli have been found in the sputa of sixty of one hundred unselected cases with cough. In about one-half of these sixty cases the influenza bacilli were in practically pure culture.
2. There is nothing distinctive in the clinical manifestations of influenza apart from epidemics, and the diagnosis can with certainty be made only by the examination of the sputum for influenza bacilli.
3. The duration of the cough and expectoration after an attack of acute influenza does not usually exceed six weeks, but in some cases the duration is for months or years.
4. Many of the cases formerly classed as chronic bronchitis are chronic influenza.
5. Cases of chronic influenza with paroxysmal dyspnea may closely resemble asthma.
6. Chronic influenza is not infrequently mistaken for pulmonary tuberculosis.

34. **Phalangeal Anomalies.**—Lund finishes his article in this issue and remarks that while no important results of practical character have been secured by radiographic study of web-fingers, it has been demonstrated that the deformity, unlike beauty, is more than skin deep, and presents a most formidable character to the surgeon.

41 *The Office Diagnosis of the Gonococcus. G. Frank Lydston.
42 Pericarditis—Puncture—Postmortem. H. C. Fairbrother.

41. **The Office Diagnosis of the Gonococcus.**—Lydston criticises the deduction that every case where the gonococcus is found is of venereal type, and that the presence of the gonococcus is always necessary. All inflammatory affections from the urogenital mucous membrane are liable to be infectious in spite of the absence of this germ. We have no evidence as yet that the gonococcus can not be developed *de novo* in the female sexual tract, and evidence seems to show that this may be the case. He thinks the discovery of the gonococcus is only of relative clinical value, and he also remarks that the chances for innocent infection are considerably greater than those in syphilis, though he admits that his views will probably not be accepted by everyone. The ordinary office diagnosis of gonorrhea by means of the microscope is often exceedingly fallacious and misleading, and sometimes unjust.

52 A Simple Device for Holding Ligatures. Maurice Rubel.

43. **Enlarged Prostate.**—Crandon discusses the literature of the subject and concludes as follows: That the underlying cause of the usual form of prostatic enlargement and of certain forms of prostatic atrophy is slow formation of new connective tissue due to infection or to infection aggravating senile degenerative processes. The gonococcus is probably the usual specific infection, 1, on account of its frequency, and 2, because other inflammatory causes are not common in this region, and 3, because of the similarity between the histology of gonorrheal processes and those in the senile prostate. Neoplasms, fibromata and myomata, occur, but may be called rare.

45. **Landmarks in the Ureter.**—The substance of the conclusions of Robinson's elaborate article is that the ureter is not of uniform caliber, but consists generally in three isthmuses or sphincters located at points in the ureter where the projecting adjacent structures compromise its lumen: 1. The distal renal pole projecting the ureter medianward, producing what he calls the proximal isthmus, sphincter or neck of the ureter; 2, where the vasa iliaca press the ureter ventralward, producing the middle isthmus or sphincter, and this is due largely to the erect position in man and is lacking in quadrupeds; lastly, it is compromised where its distal end penetrates obliquely the muscular wall of the urinary bladder. These constrictions produce ureteral dilatation and there is a ureteral reservoir or spindle proximal to each ureteral isthmus. These are more pronounced in women than men on account of the periodic hyperemia during reproductive life, and in senescence pathologic dilatations of the lumbar and pelvic spindles are likely to occur with senile sclerosis or calcification. Calculi are liable to lodge at the ureteral isthmuses, and torsion of the ureter may easily compromise the ureteral neck or proximal isthmus. Surgical intervention on the ureter should be performed at the ureteral reservoirs or spindles on account of their ample lumen and wall. Pathologic conditions of the ureter are mainly in defects of the ureteral wall, producing deficient peristalsis, or in the mechanical obstruction to the ureteral stream. So long as ureteral peristalsis is not interfered with and the stream is not obstructed, the function is normal, but whenever either of these factors exist, the non-drainage induces residual deposits with resulting bacterial accumulation, hence the resulting vicious circle, exactly similar to that from the same defects of obstruction of the pylorus or bile ducts. The ureter is an independent organ conducting urine to the bladder by rhythmic waves, regardless of altitude or force of gravity. It has similar functions to the bladder; being located in a universally loose areolar bed, and being longer than the distance between its ends, it is capable of extensive range of motion in pathologic conditions or for surgical intervention. The irregular caliber of the ureter, dilatations and constrictions is a heritage from the Wolffian body enhanced by environments.

46. **Rupture of the Kidney.**—Dodge treats the general subject of rupture of the kidney and reports his nine cases. He found the most constant and characteristic symptoms to be pain and hematuria. The latter may be intermittent or late in beginning and occasionally absent. Oliguria is often met and anuria may occur, usually due to shock and ceasing in twenty-four to forty-eight hours. Shock is also present to some extent and is often a valuable index to the amount of hemorrhage. Temperature from 100 to 101 often exists during the first three or four days, and a higher temperature may appear from simple local tissue reaction. The presence of tumor, however, is usually recognized with difficulty in the early stages, but the rigidity of the back and flank muscles is characteristic. Where hemorrhage takes place into the peritoneal

cavity characteristic signs are often evinced on palpation and percussion. Later, general peritonitis may be present. If suppuration occurs in or about the kidney, rigors, temperature, sweating, and later exhaustion, make themselves evident. The complications and the diagnosis are also noted. The latter is usually easy with the history of the case. In uncomplicated cases the course is usually a mild one, convalescence beginning from two to ten days after the acute symptoms. Two or three weeks probably represent the average duration of the case, though pain may exist longer and the danger is greatly enhanced by a rent through the peritoneum and hemorrhage into the cavity. If there is marked extra-capsular hemorrhage the prognosis is generally aggravated unless early operation is resorted to. In the simple cases, if there is only slight or moderate hemorrhage, treatment is expectant, absolute rest, milk diet, local cold applications, the use of internal remedies for the control of hemorrhage and if the employment of the catheter is necessary, the strictest antisepsis being all that is required. If there are extensive accumulated clots in the bladder their removal by a suitable evacuator is indicated. The conditions that demand exploratory incision after the lapse of the first forty-eight hours are evidences of continued hemorrhage, persistent anuria, septic symptoms, etc. The transverse incision of McBurney is best adapted to these cases. The operation may be suturing, packing and partial or total removal of the organ according to the severity of the injury. Contraindications, of course, are injury, disease, absence or malformation of other kidney.

47. **Rupture of the Spleen.**—Eisendrath reports a case and finds that the mortality has been steadily reduced with experience with the operation, which is always required, though the general prognosis of the condition is bad.

48. **Duodenocholedochotomy.**—Thienhaus concludes that the transduodenal route has a well-defined place in the surgery of obstruction of the common duct produced by gallstones, and the method of its originator, McBurney, or that of Collins by dilatation of the papilla, are the methods *par excellence* for all cases of gallstones impacted at or near the opening of the papilla as soon as experiments of manipulation have proved unsuccessful. It is also indicated for stone impacted in the retroduodenal portion of the common duct or before the diverticulum of Vater, as soon as efforts to dislodge the stone up into the supraduodenal portion have proved futile. In all cases where the operation has been performed it is advisable to suture the common duct to the duodenum to avoid infection. Choledochotomia transduodenalis seems to be more advisable than choledochotomia retroduodenalis as it is more easily performed and does not interfere with the pancreas. It has not been proven that transduodenal choledochotomy has a greater percentage of fatalities from septic infection than supraduodenal choledochotomy. Further data are desirable.

51. **Tuberculosis of the Parotid Gland.**—The rarity of primary tuberculosis in this organ is first noticed by Frank, who adds a case to the eight already recorded, and discusses its symptoms and pathology. The prognosis is good with operative treatment. Total extirpation of the gland is not necessary for a cure. He concludes with a tabulation of recorded cases.

57 Death from Meningitis Following Enucleation of the Eyeball. M. V. Ball.
58 Papilloma tous Degeneration of the Conjunctiva. H. V. Würdemann.

53. **Connective Tissue of the Orbit.**—Howe's paper is a study to ascertain more exactly the location of connective tissues found in the orbit, their relation to strabismus, and operations for its correction. He holds that the fascia and even the finer bands are of clinical importance in relation to the accumulation of fluid or the extension of morbid growths, or in the protection they give from injuries or bacterial invasions, and are also of interest in relation to the normal motion of the globe. He reviews the literature, and finds that the term capsule of Tenon does not cover any exact conception. The difficulty is in recognizing the more delicate fibers, ordinary dissection having given rise to confusion, but these fibers are of unquestioned clinical importance. By using some new methods of staining connective tissue, more especially the use of potassium permanganate and oxalic acid, we have one of the best methods for identifying these connective tissue fibers and gaining a better idea of the capsule of Tenon, insertions of the recti, check ligaments and of other connective tissues in the orbit, which are of importance as regards the more practical points and in some respects the findings are new. He finds the capsule proper of Tenon extends a little beyond the line of insertion of the recti. He also outlines more exactly the external and internal check ligaments and inferior and superior check ligaments, some of which have a decided interest in connection with the operations for strabismus, etc.

54. **Toxic Amblyopia.**—Nuel reviews and criticises Birch-Hirschfeld's studies on toxic amblyopia, and filicic and quinin, and also reviews Holdon's experiments on methyl amblyopia. He comes to the conclusion that the trouble in these cases is due to a parenchymatous neuritis and that in alcoholic nicotine amblyopia it is of double, nerve and retinal origin. The argument against the parenchymatous nature of the affection, that it can not be followed by such marked recovery, is, he thinks, erroneous.

56. **Cataract.**—Keiper gives the replies to questions made to a number of ophthalmologists as to the time and conditions for the removal of ripe senile cataract and the results. He urges the removal of the ripe senile cataract, irrespective of the condition of the other eye, because the patient has a larger field of vision, rendering him less liable to the accidents of defective sight; the dangers and difficulties of extraction of an overripe lens are avoided; it offers continuous vision as the other lens is usually affected, and the patient is more comfortable with vision in both eyes, and the cosmetic effects are better.

60 *Report of a Transverse Lesion of the Mid-thoracic Segments Leaving Intact the Posterior Columns, and Causing Syringomyelic Dissociation. Adolf Meyer.
61 A Case of Combined Sclerosis of the Spinal Cord. Frederick T. Simpson.

59. **Acute Myelitis.**—Collins reports a case commencing with symptoms of acute rheumatism and followed by myelitic symptoms, showing in the autopsy septic manifestations, extensive purulent leptomeningitis and inflammation of the cord, particularly of the lower dorsal segment. The bacillus of tuberculosis was found in portions of the lesions. He thinks that the apparent rheumatic symptoms were only the beginning symptoms of tuberculous infection of the cord.

60. **Transverse Lesion of the Cord Not Involving the Posterior Columns.**—The case reported by Meyer is of interest in regard to certain symptoms of sensibility, etc. There was practically a destruction of the cross sections of the fourth to sixth thoracic segments, leaving intact only the dorsal two-thirds of the posterior columns and a few pyramidal fibers. The tactile sensibility, pressure sense, tickle sense and sense of position were normal. Analgesia and thermanesthesia existed below the sixth rib on the right and fifth rib on the left, and a slight thermo-hyperesthesia over the fourth rib. Occasionally a girdle sensation occurred and there was paralysis below the thorax allowing but a slight pull on the thigh and toes and upper end of the recti. There was also occasional involuntary pulling up of the thighs, sometimes accompanied by shooting pains. The functional bearing of the disease on some conditions of conduction of temperature and weight sense are noted.

67 *The Pathology of Eclampsia, with Photomicrographic Illustrations. Greer Baughman.
68 Gastrointestinal Hemorrhage of the New-born—Case Treated with Normal Salt Solution and Gelatin, One-half 1 per cent.—Recovery. John F. Moran.

62. **Pregnancy Simulated by Tumors.**—Kelly reports cases of confusion of diagnosis, and points out the misleading symptoms. The mimicry of pregnancy by tumors is very close, but there are certain diagnostic signs always present. The first is absence of fetal pulse and the synchronism of pulsation of the tumor with the radial pulse. Other important points are the continuance of menstruation and the unaltered hard cervix. A careful examination for ascites and a recto-abdominal bimanual examination under a brief anesthesia will help to clear up the diagnosis. A better knowledge of abdominal palpation in advanced pregnancy will be valuable. The age of the patient and the length of time elapsed since the appearance of the tumor, absence of regular enlargement of the womb, the non-occurrence of labor, etc., are also mentioned.

63.—See abstract in THE JOURNAL, xxxix, p. 1339.

64. **Myoma of the Ovary.**—Baldy reports a case in which ovarian substance was converted into a neoplasm, assuming all its anatomic relations and still containing some ovarian tissue.

65. **Treatment of Extra-Uterine Placenta.**—In a case reported by Van de Warker an operation was performed and the placenta found distributed over an extensive area, estimated at over a square foot. Its removal in the septic and weakened condition appeared to invite a hemorrhage that would quickly prove fatal. It also seemed dangerous to close the wound with any of the usually practiced means of drainage. He therefore left the wound partially open, closing the peritoneal cavity by stitching the free edges of the sac to the peritoneum and placing in the cavity large folds of sterilized gauze. The following day the placenta was attacked with injections of 1 to 1000 solution of formalin night and morning. After about three days' gentle traction was made on the cord, and daily thereafter by means of a long curved fenestrated sponge forceps, piece after piece of the placenta was removed, the cavity contracting accordingly. When the last portion was removed, some eleven days after the operation, the degenerated edges of the wound were cut away and the wound closed. Primary union occurred.

66. **The Lymph Glands in Uterine Cancer.**—From a very extensive study of the literature, Gellhorn finds a remarkable inconstancy in the distribution of the lymph system, even under normal conditions. Carcinomatous degeneration produces in the majority of cases a marked change in the macroscopic aspect of the glands. The fact has been brought out that in about one-third of all the cases of uterine cancer involvement of the regional glands in the pelvis takes place. This occurs rarely in the incipiency of the disease and usually only after primary cancer is more or less advanced and extended into the parametria or other adjacent structures. Recurrence after the old methods of operating takes place in four-fifths of all cases in or near the cicatrix of the vagina, while it occurs in only one-fifth in the glands. Abdominal radical operation, with removal of the pelvic glands, strives to lessen the high percentage of recurrences, but so far has not been successful. This deficiency depends on anatomic and technical difficulties in routine ablation of pelvic glands. In a large number of cases this radical procedure, with its great and manifold dangers, has been found to be unnecessary, as there were no diseased glands anywhere within the pelvis. These conclusions, however, are not yet definite, and many questions are still in suspense. The future of abdominal operations will depend on laboratory researches and practical experience, the former showing what percentage and how early involvement takes place in uterine cancer and which forms of carcinoma lead to lymphatic infection and which glands are most frequently involved. Practical experience will in due time tell us whether recurrence can be made less frequent and the mortality diminished. The paper concludes with a lengthy bibliography.

67. **Eclampsia.**—Baughman gives the characteristic pathologic findings from a review of the literature. The kidneys always show evidences of degeneration and the liver is studded with punctate hemorrhages, thrombi and degenerated epithelium. The mucous membrane shows punctate hemorrhages with necrosis of the epithelium. Similar lesions are found in the heart; not so frequently in the suprarenals, pancreas, and gastrointestinal tract. The paper is illustrated with microscopic sections from a case of eclampsia, showing uterine, kidney and hepatic tissue.

70. **Red-Blood Corpuscle Thrombi.**—The following are Flexner's conclusions:

1. The agglutination of red corpuscles *intra vitam* is not uncommon in infectious disease in man and animals. 2. A special variety of thrombi is produced through this agglutination which may be denominated agglutinative thrombi. 3. When such thrombi are old, or when the agglutination is compact, they may present appearances to which the name of hyaline thrombi has been applied. 4. Other alterations of the blood than those arising in infectious disease may bring about agglutinative thrombosis, the nature of this alteration being little understood. 5. Poisons which destroy corpuscles rapidly are provocative of agglutinative thrombosis. 6. The so-called fibrin ferment thrombi are probably nothing else than agglutinative thrombi.

71. **The Permeability of the Berkefeld Filter.**—Wherry has experimented with three sizes of the Berkefeld filter to determine the time in which bacilli and bacteria can pass through and the time it requires for them to grow through the substance of the filter. His summary is given as follows:

1. The bacillus producing pneumonia in guinea-pigs will pass through the pores of the small Berkefeld filter, No. 5, under the conditions of the experiments noted. It did not pass through the larger Berkefeld, No. 8, perhaps on account of the greater thickness of the walls, the relatively small amount of the fluid passed through, and the somewhat diminished pressure. Nor did it pass through the Pasteur-Chamberland bougie. It is probable that these filters, especially No. 5, will be found even less efficient when very turbid, concentrated cultures are passed through. This was the case in Smith's experiments cited above.
2. *Bacillus coli communis* did not pass through any of the above filters.
3. *Bacillus coli communis* and the organism from pneumonia in guinea-pigs grows through the walls of the Berkefeld filter very rapidly; through the walls of the Pasteur rather slowly.
4. It seems justifiable to conclude that if the virus of a disease passes through the pores of the Berkefeld it is not necessarily ultramicroscopic. Further work with organisms of various size might help in defining the size of the pores of such a filter and determine whether various filters of the same make have the same size pores or not.
5. It would seem advisable that workers should make a preliminary test of filters, by employing some such minute organism, in order to determine more accurately the efficiency of the filter used.

73. **Subinfection by the Colon Bacillus.**—Experiments on rabbits, one set of which received small doses of culture of the non-virulent form of the *Bacillus coli* injected into the abdominal cavity, while the other received a smaller amount of a similar culture injected directly into the circulating blood through an ear vein, gave rather striking characteristic results. Charlton finds this "subinfection" of rabbits produced a marked and progressive anemia indicated by reduction in the number of red corpuscles, poikilocytosis, appearance of nucleated red corpuscles, reduction of hemoglobin, etc., together with progressive ascending paresis, ending in paralysis. The condition is very similar to that of pernicious anemia, but differs from that in the fall of the amount of hemoglobin

being parallel with the decrease of the red blood corpuscles, and in the absence of a distinct Quincke's siderosis, and of clear evidence of inflammatory or other disturbances of the digestive tract, and of changes in the bone-marrow.

80. **Anemic Infarcts of the Liver.**—Understanding by these the area of necrosis due to shutting off the blood supply, Baldwin discusses the literature and reports a case with elaborate postmortem examination. He found it was a case of multiple anemic infarction of the liver, accompanying similar conditions found in other organs. Such infarctions occur but rarely, and then only when the liver labors under such disadvantages that it can not overcome the results of an embolism or thrombosis in its congested hepatic vessels.

Mississippi Medical Record (Vicksburg), December, 1902.

82 Strangulated Umbilical Hernia: Report of a Case. Louis Frank.
83 *Some Experiments with Quinin. H. N. Stilphen.

83. **Quinin.**—Stilphen has experimented on himself with quinin, testing the amount of urine and urea passed with various doses, also regulating the diet and drink. The object was to find the action of quinin on the kidneys by comparing the results obtained during the two weeks of the experiments. There was a marked diminution in the amount of urine with increase of urea on the second week, showing that 20 gr. doses of quinin will affect the kidneys. From this he would say that the use of quinin is contraindicated in all forms of acute and chronic affections of the kidneys and liver, especially in acute uremia, liver atrophy, hematuria, yellow fever, etc.

84 *Ein Fall von schwerer Verbrennung mit hydriatrischen Bemerkungen zur Behandlung der Brandwunden. Friedrich Grosse.

84. **Treatment of Burns.**—Grosse describes a severe burn in a child aged 7, involving the face, neck, breast and both hands and over a portion of its surface destroying the stratum papillare. The patient was first treated with carron oil applications, but when he came into Grosse's hands, he used applications of absorbent gauze wrung out of a 1 to 2000 chinosol solution, with the best results and a very considerable diminution of the scar. He remarks in favor of moist applications of this kind in preference to the oily ones, covering them with water-proof material and applying them tolerably warm. He does not favor cold applications. He discusses the subject from the point of view of the literature, and remarks, in closing, that similar applications are valuable in other kinds of wounds.

93 Chronic Sphenoid Abscess. Lewis S. Somers.

85.—See abstract in THE JOURNAL, xxxix, p. 857.

87. **Corneal Tattooing.**—The technic of this operation is described by Borsch, in which he advocates the use of the single needle and the importance of not rubbing the eye to remove the excess of ink, but allowing boric acid solution to flow over it. He urges also the importance also of following the outlines of the structures underneath and imitating the normal eye as much as possible. The striations of the iris should be followed and the darker tints of the iris obtained by making perpendicular thrusts between the striations; the closer they are, the darker the tint. In this way the eye may be made to assume the color of the iris covered by the leucoma so that in many cases it is impossible to distinguish the actual condition except by the closest scrutiny. He also remarks on the notable improvement in vision that sometimes follows tattooing of the smaller opacities, and says in conclusion that many patients now wearing artificial eyes might have retained their natural ones if the possibilities of tattooing were more generally known.

88.—See abstract in THE JOURNAL, xxxix, p. 791.

90. **Epilepsy and Eye Strain.**—What Reber proposes to show is that various cases of epilepsy have continued to have their seizures with uninterrupted frequency, notwithstanding the faithful use of carefully adjusted glasses, but that in a certain percentage of cases the seizures can be diminished in frequency, and sometimes made to disappear entirely by resorting to prism glasses and exercises, or as a last resort to tenotomy—and all this without drug treatment. He does not accept the enthusiastic claims of Stevens and Ranney, but thinks that the condition of the eye nevertheless is worthy of the most careful attention in many epileptic cases. He reports a number.

99 A Case of Cutaneous Horn. Alfred E. Diehl.

95. **Diet in Asthma.**—Jack insists on the importance of a properly selected and individualized diet, as this disease depends on the functions of the blood and lungs, the blood carrying the alimentary substance throughout the system, and itself undergoing very important modifications in the lungs. He thinks that asthma is always on the borderland of severe blood conditions, such as leukemia, pernicious anemia, cerebral hemorrhage and hemorrhagic conditions of the respiratory mucosa. On account of these vicious, progressive tendencies a diet must be given such as will replace the waste of the disease and prevent intestinal fermentation and putrefaction. It must be of such a character that it will not, after absorption, readily undergo perverted chemical metabolic changes in the blood. It must also be of such a character that it can be persisted in for many years. The misery of the disease, and malnutrition from impoverished blood causes melancholia, which in turn materially interferes with the digestive function. He reviews the various types of asthmatic lymphocytosis, asthmatic toxic leucocytosis and asthmatic anematosis. In the former case he thinks in children it is advisable to completely or partially substitute the bottle for the breast, especially in cases of breast-fed infants with prominent cyanotic attacks of increasing severity. In toxic leucocytosis he would carefully watch the stools, blood and urine, as well as the general condition of the patient and give a fairly elaborate diet without much sugar, but largely composed of vegetables, which he enumerates. Animal foods are most apt to cause deleterious changes in the intestines, and if the stools become alkaline they should be diminished, while if they become acid the carbohydrates should be limited. Meat should also be interdicted or diminished if there is a marked leucocytosis exceeding that of the normal digestion, but if there is iodophilia of the blood, then carbohydrates should be cut off. His conclusions are:

> If on a differential count the blood shows a high percentage of small lymphocytes, milk should be diminished or withheld. An abnormal increase in the polymorpho-nuclear neutrophilic cells indicates an intestinal toxemia and putrefaction which suggests the withholding of meat foods. A pronounced iodophilia indicates an amyloid or starchy degeneration of blood and suggests the withholding of foods rich in starch. A thin, watery blood with a deficient plasma and a red corpuscle poor in hemoglobin and deficient in biomagnetism, as shown by the lack of rouleaux formation and the scattering of the red blood corpuscles about the field, indicates the giving of fresh bloody meat, raw eggs and green vegetables rich in chlorophyl and protoplasm.

97. **Cecal Inflammation.**—Creveling calls attention to the importance of inflammation of the cecum in many cases where the appendix gets the blame. The latter may be found healthy, even when the bowel itself is diseased.

101. The Aleuts.—This article by a layman describes the habits of the Aleuts, showing the excessive mortality among them since they have come in contact with the whites and have changed their habits and clothing. Their mode of living has never been exactly sanitary, but under present conditions the effect on their statistics is much worse; consumption especially is increasing among them. While their dwellings would seem to favor the conditions of typhoid, it seems to be unknown among them, and the filth diseases that infect even the cleaner cities are hardly present in Alaska among the natives. Their drinking habits, where they can get alcoholic liquors, are bad. This also is deteriorating the race.

1. Iodoform Gauze Plugging.—Von Bergmann describes his method of plugging with iodoform gauze in resections of the upper jaw, operations on the tongue and total extirpation of the larynx. He leaves the tampon undisturbed in the jaw for several days—even as long as ten days—before removal, and on removing finds the wound partially cicatrized and the remainder with healthy granulations. He has been fortunate in avoiding infection of the wound in this way in every case, except one in which erysipelas occurred. To avoid pneumonia from aspiration he has performed preliminary tracheotomy and plugging of the trachea in most cases. In extirpation of the tongue by Langenbeck's method, he tampons the whole wounded surface. In total extirpation of the larynx he plugs the large wound cavity on either side of the pharynx between it and the lateral muscles of the neck with iodoform gauze, which very soon adheres firmly by suction. At present he considers that an essential part of the after-treatment consists in completely shutting off the trachea from the oral and pharyngeal cavity by suturing it to the external skin at the lower angle of the mouth and by forming two lateral cutaneous flaps, which are then united above the trachea with the posterior circumference of its transverse section, thus enclosing the trachea by skin. To avoid the flowing of saliva or mucus into the trachea from the part of the wound which lies above these two flaps he carefully stuffs that part with iodoform gauze tampons. He finds the value of plugging with iodoform gauze most strikingly shown in excisions and resections of the rectum, where he stuffs the

entire wound cavity around the rectum, leaving it undisturbed for six to eight days.

2. **The Lister Method.**—Lucas-Championnière gives the history of Lister's work, showing that the failures that have been made have been from infidelity to the principles laid down by him. He is severe in his remarks on the rejection of antisepsis. Asepsis is not a new discovery; it is simply the carrying out of Lister's ideas and the neglect of antisepsis always involves the exposure to infection.

3. **Cerebral Localization.**—Eight cases are reported by Durante, 6 for dural and cerebral neoplasms and 2 for remote post-traumatic conditions, with 8 cures, 5 complete and 3 with defect. He discusses the effect of lesions of the frontal, or especially the prefrontal lobes, and calls particular attention to one of his cases, in which there was total anesthesia of the whole of the left arm from traumatic depression of the hinder portion of the right parietal bone. On removal of the depressed bone sensibility was completely restored in six hours. He considers that this case has a value as a physiologic experiment on man. The depression was situated 3 cm. distant from and behind the Rolandic fissure, that is, completely removed from the psychomotor zone and well in the parietal lobe. The baric and stereognostic, as well as the thermic and tactile sensibilities were completely abolished, and yet the restoration occurred within the short period mentioned. He thinks this is the only case in the literature that clearly proves that the center, at least for the superior extremity, of these sensibilities is situated in the parietal lobe. His conclusions are given as follows:

> That lesions, especially those determined by neoplasms, of the frontal lobes are nearly always accompanied by very grave phenomena of altered intelligence; which proves that the frontal lobes, and particularly the prefrontal, must be considered as the seat of the most elevated functions of the mind. 2. That the cortical center for hearing is situated in the temporal lobes, that each center is in relation with both the auditory nerves, and that the direct auditory bundle must be very much less active and smaller than the crossed auditory bundle. 3. That the site of the center for general sensibility and for muscular sense is in the parietal lobes, and that disturbances of general sensibility and of the muscular sense may occur in the limbs independently of any disturbance of motility whatsoever. 4. That for the solution of various problems concerning the functions of the several regions of the human brain, operative surgery and pathologic anatomy are more useful than experimental physiology, which has animals only at its disposal; the functional arrangement of the brains of such animals has some analogy with that of man, but certainly can not be compared with it in every respect.

5. **Fractured Patella.**—The results in 45 cases of fractured patella observed in the last twelve years by Von Mikulicz-Radecki in the Breslau Hospital form the subject of this article. He describes the different forms of fracture, the pure blow fracture or the tear, especially in reference to the question of whether suture of the patella is necessary or not. With few exceptions he would abstain from suturing the fractured patella in blow fractures and limit himself to medico-mechanical treatment and rest in the condition. In tear fractures, where the ligaments are torn apart, he has employed suture. He operates without exsanguinating the limb, making the incision correspond to the line of fracture and long enough not only to expose the patella, but also the torn patellar ligaments. This incision is better than the longitudinal one on account of the clear view it gives. Latterly he has used brass wire suturing, avoiding carefully any sublimate solution, putting three or four sutures in the bone, the accessory ligaments being sutured on each side with one or two sutures as well as the patella. In all, five to eight sutures will be applied. The blood-clot is removed with a sharp spoon during irrigation with sterile boiled salt solution. Drainage is not inserted, but the wound is closed, except for 1 cm. at each end of the skin incision, which remains unsutured. This is sufficient to allow the escape of any subsequent oozing, and does not prevent healing by first intention. In late operations there is less difficulty in bringing down the ends of the bone, and he has relieved the tension of the muscle by making a V-shaped incision in it, and later restoring its continuity by sewing up the edges of the cut with strong catgut sutures. The results are analyzed and generally seem to be thoroughly satisfactory.

6. **Infective Arthritis.**—The Bradshaw lecture by Marsh begins with a historical sketch, and then reviews the various forms of microbic arthritis, pneumococcic, typhoid, scarlet fever, influenzal, erysipelatous, glanderous, etc. He describes the infective joint changes and the unclassified infective arthrites and reports cases. In conclusion he remarks that the first form of infective arthritis mentioned, that which consists of transient synovitis with slight effusion, has a good prognosis and a suitable splint and warm fomentations are all that is required. Where the joint cavities, however, contain fluid, it must be removed and the joint thoroughly irrigated with carbolic solution 1 to 100, or mercurial solution, of which the best has been biniodid 1 in 1000. A full-sized hydrocele trocar may be used and irrigation through the canula or incision be employed. If the fluid is purulent the joint must be thoroughly drained, and any adhesions broken down with the finger followed by copious irrigation. In the third or plastic form, the prognosis is distinctly unfavorable and here the arthritis is but one of the manifestations of the general septicemia and is often associated with other lesions; it is also highly unfavorable. In fact, it is often only an unimportant complication of the general condition, with its fatal termination.

12. **Pneumonia.**—In his fourth Croonian lecture Washbourn discusses the question of the inhalation of fine particles by the lungs and gives details of his experiments; the mode of their introduction into the lungs is the special point. The bulk of evidence favors the view that no absorption of particles takes place through the mucous membrane, trachea and bronchi. It is probable that they go through the alveolar walls. The two chief lines of defense against the entrance of particles are the nose and the larynx. The mucosa over the turbinal bone retains an enormous amount of dust. Tracheotomized animals, therefore, are not in a favorable condition to estimate this question. Violent respiratory movements facilitate the entrance of dust into the lungs, and may lead to rupture of minute blood vessels. Small areas of collapse are frequently seen in the lungs of animals which have inhaled soot or dust. Particles getting into the alveoli are gotten rid of in the following manner: Some pass through into the lymphatics and either reach the bronchial glands, where they are retained, or are retained in the adenoid tissues and thence may be excreted to the bronchi by means of cells, while some are taken up by cells and thus passed into the bronchi and are ultimately extruded through the upper-air passages.

13. **Typhoid Thrombosis.**—The thrombosis in typhoid fever is thought by Wright and Knapp, from the results of their experiments, to be due to the excess of lime salts in the blood of typhoid convalescents. Increased coagulability may depend on this excess. The remedy is citric acid, which, for prophylaxis also, might be initiated as soon as the danger of intestinal hemorrhage has been surmounted. A partial decalcification of the milk in the diet might be wise. This can be

readily effected by adding to the milk from 0.25 to 0.5 per cent. of citrate of soda (from 20 to 40 grains per pint).

17. **Hypopyon Kerato-Iritis.**—Burnham relies on the purely constitutional treatment for severe cases, save the dropping of a 4-gr. solution of atropin every day or two and the casual bathing of the eye with a little hot water or boric acid. It consists in the use of mercury or iodid of potash taken internally and pilocarpin given hypodermically. The results, he says, have been exceedingly satisfactory.

21.—See also ¶6, above.

22. **Appendicitis.**—Lockwood is not in favor of operation in all cases. He calls attention to the relative importance of the pulse and temperature, the pulse first, temperature next, and after these the respiration. Generally one need not be alarmed if the temperature is 102 and the pulse 90, but if the pulse is 130 and the temperature 99, the condition would be alarming. The main points to be taken into consideration as regards operation are the mode of onset, including the intensity, duration of pain, rigor and vomiting, pulse, temperature and respiration, conditions of constipation or obstruction, the different forms as regards tenderness, rigidity, hardness, edema, etc., mobility of the abdominal walls and intestines, micturition, inflammatory swelling, the presence or absence of complications, such as colitis, nephritis, cystitis, pleurisy, pneumonia, subdiaphragmatic abscess, hepatic abscess, pyemia, septicemia, tubercle, actinomycosis and malignant disease. Pregnancy is an occasional and serious complication. He thinks when we are in doubt, it is better to operate. He does not believe in opiates in the medicinal treatment, and has gradually become more averse to the use of purgatives. He would remove the appendix in every case where it is possible. Biniodid catgut he finds thoroughly efficient for securing the bleeding vessels, the meso-appendix, the stump of the appendix, the omentum, and, finally, the layers of the abdominal wall. Silk and silkworm gut are not satisfactory in sepsis. If pus is found the wound should be drained and he would use gauze or a rubber drain. He also considers the expediency of incising and emptying the intestine when there is distension due to peritonitis, and considers it a safe procedure. The opening closes if there is no occlusion of the intestine beyond.

24. **Alkaptonuria.**—Garrod has studied a number of cases of alkaptonuria, paying particular attention to history, consanguinity of parents, etc., and suggests the possibility of its being a sort of metabolic sport or individualism of metabolism, not the result of a pathologic process. The thought presents itself that these are merely extreme examples of variations of chemical behavior, which are probably everywhere present in a less degree. The individuals of species do not always conform to an absolutely rigid standard of metabolism.

31 *Is "Malarial Cachexia" Purely Malarial? Leonard Rogers.
32 *Is Antivenene of Any Value in Cobra Poisoning? P. Carr-White.

28. **Mycetoma.**—This has usually been considered a local disease, but Maitland gives facts and cases which seem to indicate that in many cases it becomes complicated with secondary centers of disease due to transmission of diseased particles along the lymphatic vessels.

31. **Malaria.**—Following the suggestion that there can be secondary infections aiding in producing what is called malarial cachexia, Rogers has investigated the pigmentation of the viscera, and leucocyte variation in these cases. He calls particular attention to the leucocyte changes in malarial cachexia and their diagnostic importance, the phagocytes becoming so gradually reduced in the chronic forms of malaria strongly suggesting a persistent light between them and the parasites, and he thinks our efforts should be directed to the increase of the white corpuscles, especially the polynuclears, while giving quinin hypodermically. The great destruction of polynuclears will account for the frequency with which malarial cachexia cases succumb to the invasion of other infections like pneumonia, dysentery, phthisis, etc.

32. **Antivenene.**—Carr-White has experimented on dogs with Calmette's antivenene and finds very little profit from its use in cobra poisoning. In most cases of snake bite the species is not known, but he was most careful in his experiments to make sure as to this point. He thinks it is possible that the special antivenene of Calmette is not directly applicable to producing immunity to the Indian cobra. The question whether we will have to use different antivenenes for each kind of poisonous snake bite would seem to complicate treatment, but there appears to be no reason why antivenene for each division of poisonous snakes (colubrine and viperine) should not be used.

34. **Primary Multiple Cutaneous Gangrene.**—Carle analyzes the few cases of this affection that have been published and one he has had occasion to observe during the last two years. In all there was a history of some preceding traumatism in exceptionally robust persons, a burn or scald, a cut or the sting of some insect. The affection commenced at several points at once, the patches of efflorescence separated by long distances. The course is by recurring "pushes," which may be local or diffuse. The infectious character of the affection is established by the fever, headache, inflammation and suppuration of ganglia and glands, contagion by auto-inoculation, and erysipelatous condition of the face which accompany the exacerbations. In two cases recovery was complete in two months; in the others the attacks recurred indefinitely, but the general health did not suffer much, although Carle's patient has lost more than thirty pounds in a year and a half. He gives cuts of the patches on back and arms of his patient.

51 *Extirpation intracapsulaire de la prostate hypertrophiée. Rydygier.
52 Report of French Congress of urology.

36. **Macroscopic Anatomy of Prostate.**—Albarran's article describing the conditions that prevail in an enlarged prostate, is illustrated with forty-six cuts.

37. **Spontaneous Necrosis of Testicle.**—Senile gangrene, or apoplexy of the testicle is usually due to torsion of the spermatic cord, to infection, to phlebitis and thrombosis or to obliterating endarteritis of the spermatic artery. In the case of spontaneous and hemorrhagic necrosis reported by Mauclaire in this communication, the last-mentioned was evidently the cause of the lesion.

38. **Surgical Intervention in Medical Nephritis.**—Pousson states that he has operated eight times on 6 patients with chronic nephritis. Two were in the last stages of Bright's disease and have died. The others were remarkably improved and a complete cure can be claimed for at least one case in which nephrotomy and then nephrectomy were performed more

than two years ago. He tabulates the details of 27 published cases in which one or both kidneys were operated on. The mortality was nil. The fact of the comparative frequency of the restriction of the lesion to one kidney is a potent argument in favor of operative intervention. Both kidneys can be operated on at the same time or after an interval without danger and with great possible benefit. An operation on one kidney frequently restores the functions of its mate, even if the anatomic lesions do not retrogress.

39. **Bladder Urine Separator.**—Cathelin's instrument for collecting the urine from each kidney separately without catheterization of the ureters was described in THE JOURNAL of July 19, 1902, p. 173. The present article is profusely illustrated. Further experience is confirming the great value of this "intravesical divisor." (See also THE JOURNAL of November 8, p. 1211.)

44. **Engrafting Atrophic Testicle on Sound Mate.**—Mauclaire has thus operated on 9 patients, and the results have been highly satisfactory except in the case of a boy of 10. The other patients were adults. He assumes that some primary malformation in the vessels of the testicle is the cause of the lack of normal development. By bringing the raw surfaces of the two testicles in close contact and suturing them in a single envelope, the two organs grow together. He illustrates his technic, which consists in a lozenge-shaped incision in the tunica albuginea on the inner aspect of each testicle. In the case of the boy the ectopic testicle had not descended below the outer ring and the grafting of the sound testicle on it did not improve conditions to the anticipated extent.

51. **Intracapsular Extirpation of Enlarged Prostate.**—Rydygier formerly advocated intracapsular enucleation, but found that it exposed to the danger of involuntarily opening the prostatic urethra. This can be avoided by resection of the prostate, instead of enucleation, leaving the part near the urethra intact. His method, therefore, now is intracapsular resection through a median perineal incision, and the results he has attained corroborate the advantages of this intervention.

57 (No. 38.) Inauguration de l'hotel de l'Académie.

55. **Competition for the Audifred Prize.**—As THE JOURNAL has frequently mentioned, the Paris Académie de Médecine has an endowment representing an annual income of about $5000, which is awaiting the person who shall discover a sovereign remedy for tuberculosis. Nine communications were received in competition for it this year; six were evidently by unscientific writers. One summarized his views in the phrase, "Cool the abdomen"; another recommended consumptives to drink diluted carbolic acid; the others merely referred the Academy to persons cured by the writer's method. Three communications were from scientific competitors: Dumont described the practicability of establishing winter sanatoriums in an accessible portion of the Sahara. Bezançon and Griffin described their favorable experiences with blood gelose as a culture medium for the tubercle bacillus. V. Wachter advocated a method of treating tuberculosis by inhalation of ethylboric ether. This becomes decomposed on contact with the mucous membranes into alcohol and boric acid, and thus allows the latter to reach the mucosa very finely divided. His inhalator, designed for the purpose, is ingenious, and the results attained are very promising according to his description.

56. **Extirpation of the Rectum Without Necessity for Artificial Anus.**—Duret detaches the rectum through an abdominal incision and removes the detached intestine through a vaginal or perineal incision. He then draws down the afferent loop of intestine and sutures it directly to the anus. He describes two cases of extensive cancer of the rectum treated in this way. The patients died from their cachexia or an intercurrent cause, and at the autopsy the perfect success of the intervention was determined. He announces, therefore, that it is possible to fasten the omega loop directly to the anus without danger of gangrene or other disturbance.

75 (Nos. 91-92.) La médication ferrugineuse. Gilbert.

72. **The Practitioner and Carbon Oxid.**—When the general practitioner is summoned to a case of intoxication from carbon oxid the first measure is to carry the patient in a horizontal position into fresh air, then commence artificial respiration and traction of the tongue, with flagellation with a towel dipped in cold water. Rubbing with alcohol is also useful, but the main point is to keep up the artificial respiration and tongue traction for an hour and more, until the respiration becomes sufficiently deep and regular for oxygen to be inhaled. Ascending electricity may then be applied, if convenient, the positive pole at the anus and the negative in the mouth. In exceptional cases transfusion of blood may be a valuable adjuvant. When natural breathing is re-established the patient should be put to bed and the tendency to hypothermia combated while careful watch is kept for the reappearance of symptoms. The victim of carbon oxid intoxication looks and staggers like a drunken man. The weakness of the muscles explains the inability to escape from the room when the symptoms attract attention. The subject falls if able to rise to his feet. The after symptoms are sounds in the ears, rebellious insomnia, vertigo, tremor and even delirium. Amnesia may be absolute. Glycosuria from 6 to 15 gm. in the twenty-four hours may appear in fifty to sixty minutes after the first intoxication, and serious lobular pneumonia may rapidly develop. Nervous, vasomotor or trophic troubles may appear after a period of apparent recovery. The vasomotor disturbances are liable to be patches of erythema or nodosities which ulcerate and scab over, gingivitis, ulceration of tonsils, or unilateral edema of leg or thigh. The nervous disturbances may be a generalized or localized neuritis, neuralgic or paralytic. The paralysis may be due to an arteritis or focus of softening in the brain. It developed in Poelchen's case eight days after apparently complete recovery. The patient was 37 years old. There may also be hemiplegic neuritis, toxic hysteria or sclerosis in patches due to arteritis entailing sclerotic foci. The results of slow intoxication may be mistaken for chlorosis, hysteria, neurasthenia, "petit Brightisme," or the prodrome of softening of the brain. In examining the cadaver, sections of the muscles will sometimes give the characteristic band in the spectrum after all the carbon oxid has vanished from the blood. It may also be detected in the blood accumulating around a wound or contusion where it does not feel the effect of the oxygen in the blood. As a general rule it may be assumed that the greater the individual demand for oxygen the sooner the victim suc-

cumbs. The bird dies before the dog, while the frog does not seem to be at all affected. The child succumbs before the adult and the robust man before the women and aged. Prognosis should be guarded until two months have elapsed.

76. **Treatment of Primary Malignant Tumors of the Ethmoid.**—Moure describes a simple and easy way of obtaining access to the ethmoid. He incises the soft parts of the nose from the brows to the septum, sufficiently to one side of the median line to preserve the septum intact. He then incises the bony framework of the nose on the median line and on one side, the latter incision gradually sloping slightly toward the median line below. This allows the removal of an oblong piece, which affords ample access to the regions below, while enough of the framework is left to maintain the shape of the nose. He describes and illustrates a typical case.

77. **Direct Bronchoscopy.**—Killian's bronchoscopy has been mentioned at various times in THE JOURNAL. The present description of it is profusely illustrated, including a cut of a phantom bronchus for practice.

81. **Technic of Paraffin Prothesis.**—Eckstein proclaims that the paraffin can be kept from hardening in the syringe by ejecting two or three drops after it is filled, and aspirating the same amount of hot water. He also has found it necessary sometimes to scrape out a little of the paraffin if it spreads beyond the desired point. This is easily done and the scar of the minute incision is invisible.

89. **Abdominal Aortitis.**—Primary abdominal aortitis is rare, but chilling of the abdomen has been known to produce it. It is usually propagated from an inflammatory process in the upper portion of the vessel or in some neighboring organ. The characteristic symptoms are the pain that can be induced at the aorta and iliac arteries, the displacement of the aorta and its mobility. The pain is localized in the wall of the vessel and may be traced along the iliac arteries sometimes to their roots. It may be so severe as to prevent any exploration of the region, but when the aorta can be taken up between the fingers it will be found abnormally increased in size and less elastic. Distension occurs more easily, but the lessened elasticity prevents resumption of the former caliber and the result is a lengthening of the vessel. As it can not stretch lengthwise, it curves on itself, forms a loop and this usually slips into the left iliac fossa. At the same time it becomes more movable. There are also a number of accessory symptoms such as contraction of the rectus which may be so pronounced in some cases as to simulate a tumor in the epigastrium, stomach troubles and vomiting, neuralgia of the diaphragm, the impossibility of lying in a physiologic attitude, the character of the arterial pulse in the epigastrium, sometimes accompanied by a reflex pulse exclusively located in the muscular wall of the abdomen. and certain disturbances in the abdominal circulation causing local elevation of temperature on slight exertion, when the mouth and axillary temperature show no change. A very important sign is hypertension in the dorsal artery of the foot, when compared with the radial tension. This indicates almost infallibly some irritation in the subdiaphragmatic arteries. On the other hand, when there is hypertension in the abdominal arteries but hypotension in the dorsal artery, the disturbances in the abdominal circulation are of a purely reflex order or are due merely to a neurasthenic condition. Teissier has been collecting data on this subject and proclaims that this modification in the peripheral blood pressure is almost pathognomonic. He calls it "le signe de la pédieuse." In all his patients there was an increase of 2 or 3 cm. of mercury in the blood pressure of the dorsal artery, while physiologically it is 20 mm. below the radial pressure. The complications of abdominal aortitis include besides the multiple dyspneic or cardiac reflexes and gastric and intestinal disturbances, a possibility of intestinal hemorrhages, nephritis from propagation of the inflammation, or actual infarctus or rupture of the aorta. Resolution of the inflammation is the rule, at least in the recent cases. The hypertension in the dorsal artery gradually subsides as recovery progresses. Treatment is principally by rest in bed to immobilize the artery and prevent displacement, and careful dieting to avert digestive disturbances which might add to the erethism of the abdominal circulation by reflex action and induce pulsation in the celiac trunk. A strict milk diet—when it is tolerated—frequently answers these indications. Revulsion is indispensable. Leeches have proved useful during the acute stage. During the subacute periods a blister or mustard plaster may suffice. If the affection shows a tendency to become chronic, small blisters frequently repeated, or cauterization with a conical cautery may be beneficial. Measures are also needed to soothe the abdominal reflex excitability and hyperesthesia. This can be accomplished with belladonna salve or conium plaster, application of compresses, injections of hot water or injections of ammonium bromid, which is an excellent remedy for the circulatory reflexes originating in intestinal irritation. Iodin and tannin will promote internal resolution and calomel may be useful both internally and in local applications.

90. **Surgical Intervention in Chronic Nephritis.**—Lépine describes experimental research on three dogs in which decortication of the kidney after venous stasis had been induced did not materially increase urination. He does not believe that capsular nephrotomy or decortication would be of much benefit in the clinic in similar cases. He would restrict it to painful unilateral congestion rebellious to medical measures, or to anuria consecutive to a congestive attack. Exposure of the kidney and decortication are mild procedures in a sound animal but are much more serious when the organ is diseased. It is important to examine the cadaver of a person with Bright's disease who has been treated by decortication, in order to learn the exact status of the intervention and its results.

91. **New Reagent for Biliary Pigments in Urine.**—Baudouin states that a solution of fuchsin added to urine produces an orange stain in case it contains bile pigments. The fuchsin must be in a .5 per cent. solution and two drops are added to a test tube one-third full of the filtered urine.

93. **Chorio-Epithelioma Outside of Region of Ovum Implantation.**—Kissel reviews 11 cases, 1 personally observed. Only 4 were fatal. In 7 the vagina and always the anterior wall was affected; in one the brain, in one the uterus and other internal organs, and in one the lungs. The deportation of the particles of chorionic epithelium may occur by way of veins or arteries, and has been observed even during the course of the pregnancy. The possibility of spontaneous arrest

and healing, even for a chorio-epithelioma with metastases, should impose caution in regard to assuming its malignant nature. In the personal case reported, exhibiting multiple chorio-epitheliomata in vagina and lungs, the lesions in the lungs healed spontaneously after those in the vagina had been excised. In a second series of 6 cases all were fatal, in 4 from recurrence after operation. The vagina or labia were involved in 5. In one the labium and lungs were the seat of the lesion, and in another the epitheliomata were found in the right and left heart, and in the small arteries of the brain, kidney and intestines. The uterus and adnexa were exempt. In this case an old interstitial myocarditis evidently favored the settling of fragments brought to the heart by way of the uterine veins.

96. **Opening of the Cavernous Sinus in Case of Thrombosis.**—Voss opened up the cavernous sinus in a recent case and recommends his technic, although the patient succumbed to the progress of his meningitis. The intervention described allows ample drainage. He approached the Gasserian ganglion, and the first and second branches of the fifth nerve, which were his guides to the sinus, by means of a flap made according to Lexer's directions. It requires temporary resection of the malar bone. After exposure of the Gasserian ganglion and of the first and second branches, he opened up the sinus with the knife, and inserted a drain tube wrapped in gauze, after which the wound was sutured. The autopsy showed that the sinus had been opened for 6 to 8 mm. In case the thrombosis originates in the orbit, the intervention can be modified as he describes to open into it. He believes that this procedure will be found useful not only for exposing a thrombosed sinus but also for the evacuation of the rare extradural abscesses at the apex of the pyramids. Further experience will establish whether it is possible to save the patients by this means, and also whether the intervention on the sinus will have to be bilateral.

98. **Simplified Process for Roentgen Stereoscopy.**—Bartholdy states that fine stereoscopic images can be seen by using ordinary 18-degree prism glasses in the stereoscope and the original plates, not a reproduction or enlargement of them. The simple apparatus consists merely of a sliding somewhat pyramidal chamber fitted to hold the original plates at the larger end. As soon as the plates are dry they are ready for inspection, and they can even be used before they are dry.

99. **Simplification of Suture in Applying Murphy Button.**—Rehm has worked out on dogs a method of suturing the Murphy button in place which materially shortens the time. One part of the button is inserted in the incision in the intestine and pressed close against one end of the wound. The incision below is drawn together by a single buttonhole suture close to the button, which is thus held firmly. If the incision is unduly long two or more sutures may be required, but if just the right length, one is sufficient. In an end-to-end anastomosis the button is inserted in the small incision and a buttonhole suture—a single stitch—taken each side of the button. In the experiments on two dogs the button was passed after four days, and when dissected, the bowel was found in perfect anastomosis with a smooth cicatrix.

101. **Operation for Uterine Fibromyomata.**—Hegar advocates vaginal total extirpation, and has thus removed tumors that extended above the umbilicus. In some cases he has prepared the uterus for extirpation by working through the vagina, and then removed it finally by abdominal section. He does not believe in retaining the uterus in case of large tumors, as its vitality is compromised, and it is possible to ligate the vessels as a preliminary measure and thus obviate hemorrhage, when there is no care as to its further function.

102. **Successful Operative Treatment of Lung Tuberculosis.**—Landerer proclaims that great benefit can be derived in advanced cases of tuberculous cavities, from resection of parts of several ribs. The cavity is not opened, and the aim of the intervention is merely to mobilize the wall of the chest over the lesion and by resecting the ribs to allow the wall to contract and reduce the size of the thoracic cavity. The lung is thus forced to contract also and is not able to expand to its former capacity. This favors the healing of the tuberculous lesion within. He describes in detail 6 cases on which he has thus operated. All were what is called hopeless cases, but the results of the operation were the complete cure for the time being of one, and probably of another; two others were very much improved, and the fifth patient was operated on recently. This method of treatment is particularly applicable for lesions in the lower lobe, which for some unknown reason offer such an unfavorable prognosis that the sanatoria usually refuse to receive them. Consequently Landerer advises this operation in such cases even in the early stages. It is surprising how well the consumptives bear the operation. The benefits are apparent in the course of two or three weeks. Chloroform narcosis is well tolerated, but loss of blood must be guarded against. The most appropriate cases are those with destructive processes which are stationary or slowly progressive. He attributes a large measure of his success to the fact that he always precedes and follows the operation with cinnamic acid (hetol) treatment, whose effect in promoting the shrinking and healing of tuberculous lesions has been thoroughly established. The operation in one case included resection of 4 to 15 cm. of seven ribs, the second to the eighth, reached through a right-angled incision in the rear side wall of the thorax, drawing the scapula forward. In the second case a triangular piece was removed, including 3.5 cm. of the first rib; 5.5 cm. of the second and 7.5 cm. of the third. In another patient, about 70 cm. of ribs were resected from the ninth to the fourth rib, but the cavity involving the entire lower lobe was too extensive for the possibility of complete healing. The patient's condition is somewhat better than before the intervention. In another case the intervention was an *indicatio vitalis*. Large pieces

were reseeted from the ninth to the fifth ribs, from the rear on the left side to the axillary line, the patient in a position to prevent pus from flowing into the sound part of the lung. There was no coughing nor expectoration afterward and the abscess had to be evacuated later from without, after which the patient rapidly improved and the benefit derived has been permanent. Landerer used the morphin-chloroform-oxygen narcosis in all. He adds also the history of three cases operated on several years ago by draining the cavity. One patient still has a fistula; the others were practically moribund when operated on.

103. **Spirometry.**—Hoesslin and Gebhardt have found that the spirometer findings vary with the same individual under otherwise similar conditions unless the air breathed is warmed to body temperature and calculated for the state of the barometer. They illustrate an improved spirometer which warms the air, and propose formulæ to remedy the defects of the Hutchinson method, according to which the vital capacity of an individual differs to a marked extent as he is at the level of the sea or at Davos, for instance, although all other conditions are the same.

104. **Explanation of Action of Atropin in Ileus.**—Pal has learned from research on dogs that atropin has an elective inhibiting action on the nerve terminals of the vagus and splanchnicus, while the muscles of the walls of the intestines and the ganglia which control peristalsis are not affected by it. As atropin thus affects only certain ganglionary apparatus for the intestines, it should be applied in those cases alone in which the elimination of these ganglia is required.

115. **Successful Treatment of Tuberculosis with Tuberculin.**—Roemisch has followed Goetsch's directions in regard to the administration of tuberculin—waiting and adapting the doses to avoid all febrile reaction—and his experience has fully confirmed the successes reported by Goetsch. He thinks, however, that besides the febrile, extremely nervous patients should also be excluded. He found the treatment effective even in quite advanced cases which had come to a stillstand as the result of sanatorium and other treatment, but which could not be forced to further improvement. In all cases in which too rapid breaking down of extensive diseased tissue might prove harmful, the use of tuberculin is not advisable. The best results are attained in cases in which the lesions have partially cicatrized.

116. **How Shall We Anesthetize?**—Witzel makes a practice of securing thorough disinfection of mouth, nose and air-passages as a preliminary to any operation. Inhalation of steam from saline solution or of turpentine he considers a most important measure for the prevention of ether pneumonia and ether bronchitis. He has the patient recline on the table with the head lowered at an angle of about 45 degrees. This allows free egress to the secretions that accumulate in the air-passages, while there is no hypersecretion in the trachea or larynx. The patient is covered with warm cloths held in place by long bags drawn up over arms and legs, so that he will not be chilled when the window is opened to ventilate the room after the operation. He is then told to count from 200 backwards, slowly and breathing deep between the numbers. Chloroform is given at first, and then ether, only a drop of either at a time. When the operation is completed the patient is carried with head still low to his bed, and allowed to sleep with the window open. He exhales ether for hours, but the fresh air, with rinsing of the mouth, will certainly diminish the tendency to vomit. If vomiting does occur the stomach is rinsed on the supposition that some ether must have been swallowed. He allows his patients to get up remarkably early after even severe operations, the evening of the same day after amputation of the upper arm, for instance, the next day after ablation of a carcinoma of the mamma, etc. All are instructed and trained beforehand to breathe deep ten to twenty times in the half hour by the clock. If the deep breathing causes pain, morphin may be needed. His experience with morphin scopolamin narcosis in 3 cases anesthetized by Korff himself, was unfavorable. One patient suffered from weak heart action afterward for days, and another succumbed to sepsis, which he might have resisted under other circumstances.

122. **The Lime-Tuberculin Treatment of Tuberculosis.**—Rudolph argues that calcification is one of Nature's means of combating invasion by a foreign body. Tuberculin given by the "Etappen" method, that is, in repeated courses, combined with administration of lime water per os and rectum, is a combination that has proved remarkably effective in his hands in the treatment of advanced tuberculosis. He reports 5 cases and the results challenge attention, although none have been controlled by autopsy findings. The lime is continued in the intervals between the courses of tuberculin, to promote calcification as much as possible.

124. **Sulphur in Typhoid Fever.**—Woroschilsky has been giving 1 to 1.25 gm. of sulphur depuratum every two hours in a large number of cases of typhoid for the protecting coating which it forms in the intestine. It has also an antiphlogistic and antiseptic action, but these are subordinate. The coating formed by the sulphur prevents irritation and injury of the intestinal walls from the ingesta. The rapid subsidence of the diarrhea and other symptoms testifies to the great benefit derived. He cites tests on healthy men who took 22 gm. of sulphur a day without injury and no disturbance of either appetite or digestion. Kobert states that 90 per cent. of the sulphur ingested passes unaltered through the system.

130. **The Pulse in the Insane.**—Roxo proclaims that the sphygmographic tracings may be able to differentiate certain dubious cases of mental affections. In laborious research on 130 insane patients he found a very pronounced difference in the pulse between certain classes of affections. It was only exceptionally normal. He reproduces the tracing of a typical example of each class. In mania the pulse was slow, averaging in 6 patients 66 to the minute. In melancholia the pulse was polycrotic and slower than normal, averaging 62 in 7 patients, but otherwise regular. The average in 14 patients with mental confusion was 82, the vertical line of the wave was very pronounced and the waves were polycrotic and very irregular. In 9 cases of dementia the average was 78 and the sphygmogram resembled that of arterioselerosis. In 11 paranoiacs the pulse beat was more rapid than normal, averaging 80. The sphygmogram is peculiar and characteristic in this affection. The

top of the wave very rounded and irregularly polycrotic. In 18 cases of epilepsy the sphygmogram was marked by a short vertical line, frequently irregular, alternating with a dicrotic wave, the beat only 66 to the minute. In hysteria the tracings were very irregular, the beat averaging 76. In 25 alcoholic cases the pulse was within the range of normal rate. The vertical line was very short and the top of the wave frequently flat. The pulse averaged 64 in the cases of cerebral syphilis and 78 in those of systematic psychoses. M. Nery has reported that he found some disturbance in the circulatory apparatus in 93 per cent. of the insane in his experience, but the characteristic differences in the pulse above noted are probably of reflex, vasomotor origin.

132. **A Diagnostic Sign of Ankylostomiasis.**—Gurgel's experience fully confirms the value of the bluish spots on the tongue as a sign of ankylostomiasis. He found them in nearly every one of a large number of patients examined.

133. **Accidents of Serotherapy.**—Cruz compares the accidents from the use of serum treatment at Rio with those reported in Europe and announces that they were identical in kind and occurred in about the same proportion. The minor accidents from antiplague serum made at Rio were digestive disturbances, cutaneous manifestations, adenitis or pain in the joints, muscles, etc. Two of the persons thus affected were physicians, and the disturbances were not sufficient to interfere with their practice, and vanished in the course of a few days. The more serious accidents included high temperature, intense pain, arthralgias, neuralgias, etc., pulmonary phenomena, delirium, prostration and adenitis accompanied with symptoms which suggested the plague. In the case of the wife of a colleague, after two injections of the serum a ganglion became painful, and there was insomnia and agitation, with temperature of nearly 103 F. and chills. A patch of erythema 30 cm. long developed, with urticaria, ecchymoses in the legs, and manifestations in the joints suggesting articular rheumatism. The patient also lost flesh; 42.5 c.c. of the serum had been injected in the course of eight days. The physicians were in doubt as to whether the case might not be true plague, but bacteriologic examination was always negative and the patient rapidly recuperated. A single injection of 10 c.c. in a woman in the seventh month of pregnancy was followed by very high temperature and swelling of glands with intense pain and purpuric patches. All these symptoms vanished by the end of fifteen hours. In another case an erysipetalous patch developed on the abdomen accompanied by fever, pain and swelling of the glands, after two injections of 10 c.c. of the serum. All the disturbances had vanished by the end of the week. Out of the total of 123 persons injected with the serum 58, or 47.17 per cent. exhibited accidents, but only 7 were of a serious character. Adenitis occurred alone or with other symptoms in 18. The serum used was about a month old. The proportion of accidents observed at Frioul was 44.7 per cent., and at Glasgow, 47.3 per cent. Among the incidents which he relates to show the efficacy of preventive antiplague injections is the case of an infected vessel, the Gundulic, which arrived with a case of plague on board. The patient was taken to the hospital and the rest of the crew were treated with the antiplague serum as a preventive measure. No further cases of plague occurred until twenty days had elapsed, when two more sailors exhibited symptoms of the disease. The ship had evidently been infected but the antiplague serum had protected the crew from infection so long as its immunizing effect lasted. This is from eight to fifteen days. After this immunizing effect had worn off, the crew were liable to contract the infection as if they had not been injected. The incident is interesting from the further fact that the two sailors last affected had the dangerous submammary bubo or plague carbuncle, and yet, possibly owing to the influence of the preceding injection, the course of the disease was exceptionally mild. All the serum prepared at the local institute is heated for an hour to 135 F., which destroys the toxic properties inherent in normal serum. No fatal accident has followed the use of antiplague serum anywhere, he concludes, and commends it as a most valuable and indispensable preventive measure.

136. **Treatment of Yellow Fever with Glucosed Serum.**—Guimaraes argues that the symptoms of yellow fever indicate insufficiency on the part of the liver. This commences by depression of the glycogenic function, the key to all the subsequent phenomena, he thinks. He aims to compensate the loss of this function by subcutaneous injection of a mixture of 10 gm. of glucose in 200 c.c. of a 1 per 1000 solution of sodium chlorid. This promotes diuresis, alleviates thirst and strengthens the heart action, as Barker has already established. Guimaraes has tried it hitherto only on moribund patients, but the effects observed encourage its wider adoption.

141. **The Pulse in Yellow Fever.**—Ferrari gives a number of tracings to illustrate the pulse in yellow fever. The ascending line is vertical and rises to a peak at first. The pulse is markedly dicrotic in the two first days, and it is very rapid in proportion to the arterial pressure in the first twenty-four hours, suggesting derangement of the innervation of the arterial apparatus. Another interesting fact is the modification in the arterial pressure after a minimal blood letting. Withdrawal of 40 to 60 c.c. of blood is immediately followed by a drop in the arterial tension, revealing the lack of arterial vasomotor reflex action. The aim in treatment should be to relieve the overtaxed heart by restoring the arterial contractility. In no other disease does the arterial hypotension succeed so rapidly to the exaggerated tension at first. The pulse in a typical case described was 110 and the tension 26 the first day, by the third they were respectively 90 and 16, by the fourth 68 and 12, and the fifth day 88 and 8.

146. **Colonial Medicine.**—In this article is reviewed the sanitary work accomplished in Havana by the United States authorities. It cites extracts from Paris papers contrasting the condition before and after the conquest of Cuba, and remarks that the "contrast is a greater blow to the good name of Spain than the defeat at Santiago and more depressing than the treaty of Paris." It also describes the instruction and institutes of colonial medicine in England and France, although as it adds, "the Spaniards have no longer the same interest as formerly in matters pertaining to colonies."

148. **Medical Deontology.**—Varona remarks in the course of his article, which is an appeal for physicians to assert certain rights, "we physicians spend half our life seeing patients, and the other half in lamenting over the conditions that prevail," instead of organizing and working to improve them.

151. **Petition to King of Spain from City Physicians.**—According to the present Spanish law each town has its city physician, who is supposed to look after the public health, but no provision is made as to their appointment, salary, etc., which is all left to the municipal authorities. They have no secure tenure of office and no means of enforcing their recommendations, and this appeal states that the public health thus left at the mercy of the municipal authorities is absolutely disregarded and thousands of lives are unnecessarily sacrified every year. The "médicos titulados," as they are called, have been holding a conference for the purpose of protesting against this state of things, and they formally petition the government to alter the law and have the public health confided to the care of a "cuerpo de sanidad civil" in each town, a board of health appointed by and responsible to the state, to the central government instead of being at the mercy of local politics.

New Patents.

Patents of interest to physicians, November 18 to December 9:

713952. Pasteurizer. A. A. Busch, R. Gull, and T. J. Barry, St. Louis.
713980. Hypodermic syringe. Henry J. Gill, Clonskeagh, Ireland.
713875. Portable stand for supporting and carrying stretchers. Harry C. Hall, Telluride, Colo.
714041. Sterilizer for liquids or fluids. Irvin E. Schoch, Damascus, Ill.
714052. Artificial leg and ankle joint. Sylvester E. Staggs, New York.
714067. Muscle-developer. Elndred Viko, Sioux Falls, S. D.
714124. Body brace. Joel U. Adams, Cincinnati.
714463. Exerciser. Matthew Duffner, Allegheny, Pa.
714477. Strength-testing machine. Henry Haenze, Pittsburg, Pa.
714305. Hernial truss. George R. House, Kansas City, Mo.
714309. Exercising apparatus for straightening the legs. Franz Langel, Cologne, Germany.
714342. Apparatus for treating diseases by vacuum and air pressure. Robert Watson, Washington, D. C.
715010. Hernial bandage or truss. Vincenzo Brocchi, Milan, Italy.
714785. Disinfecting apparatus. B. M. Davis, Los Angeles, and C. E. Cook, Whittier, Cal.
715052. Mouth and nose guard. Margaret B. Goodwin, Denver.
715112. Catamenial appliance. Theresa Minard, Scio, Ohio.
714738. Extracting syringe. Joseph R. Perry, Wilkesbarre, Pa.
714952. Applicator. Willard E. Robinson, Malden, Mass.
714850. Appliance for preventing neuresis. Carl Zimmermann, Heidelberg, Germany.
715331. Truss. Joel U. Adams, Cincinnati, Ohio.
715650. Electrical massage apparatus. Oscar A. En Holm, New York.
715661. Vaccinating tool. Elijah M. Houghton, Detroit.
715290. Device for cleaning hypodermic needles. George Porter, Manchester, N. H.
715426. Suturing instrument. David Schisgal, Vernon, France.
715701. Truss. Milton B. Smith, Holton, Kan.
715612. Wound closing device. Gerard J. Van Schott, Passaic, N. J.

The Public Service.

Army Changes.

Movements of Medical Officers, U. S. Army, under orders from the Adjutant General's Office, Washington, D. C., from Dec. 8 to Dec. 13, 1902:

Andrews, Charles H., major and surgeon, U. S. V., is honorably discharged from the service of the United States, to take effect Feb. 1, 1903, his services being no longer required.

Adair, George F., contract surgeon, U. S. A., is granted leave of absence for one month, to take effect Dec. 1, 1902.

Corbusier, William H., major and surgeon, U. S. A., is granted leave of absence for one month.

Moseley, Edward B., lieut.-col., deputy surgeon-general, U. S. A., is detailed as a member of the Army retiring board to meet at Denver.

Lewis, William F., captain and asst.-surgeon, U. S. A., is granted one month's leave of absence, to take effect when relieved from duty at Fort D. A. Russell, Wyoming.

Robins, Robert P., contract surgeon, U. S. A., now at Philadelphia, will proceed to Fort Niagara, N. Y., and report in person to the commanding officer of that post for duty and by letter to the commanding general, Department of the East.

Navy Changes.

Changes in the Medical Corps of the Navy, week ending December 20:

P. A. Surgeon T. D. Myers, retired, detached from special duty at Naval Hospital, Philadelphia, and ordered to the Navy Yard, League Island, Pa.

P. A. Surgeon E. Thompson, detached from the *Montgomery*, and ordered to duty with the marines at Culebra, W. I.

P. A. Surgeon H. H. Haas, detached from duty at Culebra, and ordered to the *Montgomery*.

Asst.-Surgeon S. S. Rodman, unexpired leave revoked, and ordered to the *Pensacola*.

Surgeon N. J. Blackwood, detached from the *Alliance*, and ordered to the *Chicago*, via steamer sailing December 27.

P. A. Surgeon C. DeW. Brownell, detached from the *Panther* and ordered to the *Alliance*.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the 14 days ended Dec. 18, 1902:

Surgeon C. T. Peckham, granted leave of absence for 14 days from December 23.

A. A. Surgeon P. N. Barnesby, granted leave of absence, on account of sickness, for 30 days from December 10.

Asst.-Surgeon M. J. White, relieved from duty at San Francisco, and directed to proceed to Portland, Ore., and assume command of the service at that port.

Asst.-Surgeon D. H. Currie, to report to Surgeon A. H. Glennan, San Francisco, for assignment to duty.

A. A. Surgeon C. W. Bailey, granted leave of absence for 7 days.

A. A. Surgeon P. N. Barnesby, granted 9 days' extension of leave of absence from December 1.

A. A. Surgeon G. A. Gregory, granted leave of absence for 10 days from November 26.

A. A. Surgeon J. C. Rodman, granted leave of absence for 4 days from December 15.

A. A. Surgeon M. H. Ross, granted leave of absence for 14 days from December 21.

Medical Inspector Agnes Walker, granted leave of absence on account of sickness, for 15 days from December 1.

Pharmacist F. L. Brown, to proceed to Philadelphia, for special temporary duty.

Pharmacist W. F. Schlaar, to report to Assistant Surgeon-General G. T. Vaughan for temporary duty in office for the port of Washington, D. C.

BOARD CONVENED.

Board convened at Boston, Dec. 10, 1902, for the physical examination of officers of the Revenue Cutter Service. Detail for the Board: Surgeon R. M. Woodward, chairman; Asst.-Surgeon W. C. Rucker, recorder.

REINSTATEMENT.

W. F. Schlaar, reinstated and appointed senior pharmacist, effective Nov. 13, 1902.

PROMOTIONS.

To be pharmacist of the third class: E. M. Holt, C. W. Stephenson, G. W. Iltis, G. A. Morris, M. H. Watters, L. P. Hall, L. C. Spangler, F. Siedenburg, C. Stier.

To be pharmacist of the second class: A. M. Roehrig, J. Achenbach, G. H. Brock, E. S. Maguire, R. H. Gibson, T. V. O'Gorman, F. L. Brown, F. S. Goodman, Charles Miller, C. H. Woods, F. R. Hanrath, S. W. Richardson, J. V. LaGrange, M. McKay, M. Walerius, W. W. Kolb, G. C. Allen, F. H. Peck, Edw. Rogers, F. J. Herty, E. B. Scott, C. Slough, B. E. Holsendorf, L. W. Ryder, M. R. Mason, F. L. Gibson, C. G. Carlton, F. A. Southard, H. E. Davis, R. F. Troxler, J. E. Beck, W. F. Schlaar.

To be pharmacist of the first class: W. F. Macdowell, Henry Gahn, W. L. Stearns, A. M. Roehrig, G. H. Brock, R. H. Gibson, T. V. O'Gorman, F. L. Brown, F. S. Goodman, Chas. Miller, F. R. Hanrath, S. W. Richardson, J. V. LaGrange.

CASUALTIES.

Surgeon John Vansant, died Dec. 12, 1902.
A. A. Surgeon Joseph Charles, died Dec. 11, 1902.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended Dec. 20, 1902:

SMALLPOX—UNITED STATES.

California: Sacramento, Nov. 29-Dec. 6, 3 cases; San Francisco, Nov. 30-Dec. 7, 3 cases.
Colorado: Denver, Dec. 6-13, 9 cases.
Florida: Jacksonville, Dec. 6-13, 1 case.
Georgia: Atlanta, Dec. 3-10, 2 cases.
Illinois: Belleville, Dec. 6-13, 1 case; Chicago, Dec. 6-13, 4 cases; Freeport, Nov. 29-Dec. 13, 3 cases.
Indiana: Indianapolis, Dec. 6-13, 22 cases, 2 deaths.
Maine: Dec. 6-13, Biddeford, 4 cases; Portland, 1 case.
Massachusetts: Dec. 6-13, Boston, 21 cases, 2 deaths; Chelsea, 1 case; Lawrence, 2 cases; Malden, 1 case; Newton, 1 death; Taunton, 3 cases.
Michigan: Detroit, Nov. 29-Dec. 13, 68 cases; Grand Rapids, Dec. 6-13, 9 cases.
Missouri: St. Louis, Nov. 30-Dec. 7, 40 cases.
Nebraska: Omaha, Dec. 6-13, 3 cases.
New Hampshire: Nashua, Dec. 6-13, 20 cases.
New Jersey: Newark, Dec. 6-13, 1 case.
New York: Dec. 6-13, Binghamton, 1 case; Buffalo, 1 case; New York, 7 cases.
Ohio: Cincinnati, Dec. 5-12, 2 cases; Cleveland, Dec. 6-13, 11 cases, 5 deaths.
Pennsylvania: Altoona, Dec. 6-13, 14 cases; Erie, Dec. 6-13, 3 cases; Johnstown, Nov. 22-Dec. 13, 12 cases, 2 deaths; McKeesport, Dec. 6-13, 1 case; Philadelphia, Dec. 6-13, 4 cases, 2 deaths; Pittsburg, Dec. 6-13, 20 cases, 9 deaths.
Utah: Salt Lake City, Nov. 29-Dec. 13, 12 cases; 3 cases imported.
Washington: Tacoma, Nov. 30-Dec. 7, 1 case.

SMALLPOX—FOREIGN.

Canada: Quebec, Dec. 6-13, 1 case.
France: Rheims, Nov. 23-30, 1 death.
Great Britain: Bradford, Nov. 15-29, 38 cases; Dundee, Nov. 22-29, 2 cases; Manchester, Nov. 22-29, 1 case; Sheffield, Nov. 15-29, 9 cases.
India: Bombay, Nov. 11-18, 1 death.
Italy: Naples, Nov. 24-Dec. 1, 2 cases; Palermo, Nov. 15-22, 3 cases.
Mexico: Mexico, Nov. 23-30, 1 case, 1 death.
Russia: Odessa, Nov. 15-22, 2 cases, 1 death; St. Petersburg, Nov. 15-22, 7 cases, 2 deaths.
Straits Settlements: Singapore, Oct. 25-Nov. 1, 2 deaths.
Uruguay: Montevideo, Oct. 23-30, 11 cases.

YELLOW FEVER.

Brazil: Rio de Janeiro, Nov. 1-8, 4 deaths.
Colombia: Panama, Dec. 1-8, 5 cases, 2 deaths.
Costa Rica: Port Limon, Nov. 29-Dec. 6, 4 cases, 3 deaths.
Mexico: Tampico, Nov. 30-Dec. 7, 18 deaths; Vera Cruz, Nov. 29-Dec. 6, 12 cases, 3 deaths.

CHOLERA.

China: Hongkong, Oct. 18-25, 1 case, 1 death.
Egypt: Alexandria, Nov. 8-22, 39 cases, 35 deaths.
India: Calcutta, Nov. 8-15, 24 deaths.
Straits Settlements: Singapore, Oct. 24-Nov. 1, 19 deaths.

PLAGUE.

Brazil: Rio de Janeiro, Nov. 1-8, 5 deaths.
China: Hongkong, Oct. 18-25, 1 case, 1 death.
Egypt: Alexandria, Nov. 8-22, 1 case.
India: Bombay, Nov. 11-18, 134 deaths; Calcutta, Nov. 8-15, 6 deaths.
India: Karachi, Nov. 9-16, 10 cases, 6 deaths.
Straits Settlements: Singapore, Oct. 25-Nov. 1, 1 case, 1 death.

TUBERCULAR PERITONITIS

IN EARLY LIFE: WITH ESPECIAL REFERENCE TO ITS TREATMENT BY LAPAROTOMY.*

THOMAS MORGAN ROTCH, M.D.

PROFESSOR OF DISEASES OF CHILDREN, HARVARD UNIVERSITY. BOSTON.

The clinical differentiation of cases of tuberculosis of the peritoneum in early life, based solely on the pathologic findings, is inadequate for a satisfactory decision, first, as to diagnosis, second, as to etiology and treatment.

It has long been known that in certain cases of tubercular peritonitis laparotomy has proved to be curative, where all other means of treatment have been ineffectual. The reason why the laparotomy is in these cases successful is not definitely known.

Tuberculosis of the peritoneum, from an etiologic standpoint, is often obscure, but it may be a primary infection. Most commonly, however, it is secondary to tuberculosis of the mesenteric lymph-nodes. Again, it may be secondary to tuberculosis of other organs, such as of the intestines, of the lungs or of the lymph-nodes in various parts of the body. It may arise in the course of various infectious diseases, especially the exanthemata. From a pathologic point of view, the process consists of the formation of miliary tubercles on the peritoneum, which give rise to opaque cheesy thickening, often nodular, and with firm adhesions of the adjacent surfaces. This pathologic condition may or may not be accompanied by an exudation into the peritoneal cavity; the ascites may be serous, sero-purulent or purulent in character and of different amounts, but the amount of fluid when any is present is usually considerable.

Again, from a pathologic standpoint, we may practically speak of three forms, first, a miliary tuberculosis with ascites acute or subacute in its course. Second. A fibrous form in which ascites may be, but is not usually present. This second form is essentially chronic, and is represented by the formation of a fibrous tissue with matting of the intestine, the omentum and the mesentery, without much tendency to caseation or to breaking down. Third. A later stage of the form just described, in which there occurs large tubercular deposits with caseation and softening. This form has by some pathologists been called the ulcerative, and in it the lungs are commonly affected. It is not so chronic as the fibrous form, but is characterized by more fever and more severe symptoms.

In view of the difficulty in determining clinically the various types just enumerated we must consider certain questions: 1. The diagnosis of the presence of a tuberculosis of the peritoneum. 2. The detection of which pathologic form is present. 3. Whether the tuberculosis of the peritoneum is localized and is not complicated by tuberculosis elsewhere (this practically means outside of the abdominal cavity), or is secondary to tuberculosis of the thoracic cavity. 4. Which of these forms of tuberculosis of the peritoneum are amenable to treatment? Finally, 5, under what circumstances and in what cases should laparotomy be performed?

The answers to these questions must be, it is acknowledged, somewhat uncertain. It is only in a general way that, with our present knowledge, we can determine clinically whether a laparotomy should be performed. The finer details, both pathologic and symptomatic, although interesting at the autopsy in the light of advancing our knowledge of the subject, are clinically of little practical value in comparison with the importance of differentiating the operable from the inoperable cases.

With this general statement we must now consider how we can solve the various questions which have just been enumerated, and finally, we must determine whether we shall or shall not operate in a given case. My views on this subject are based on a study of those cases of tubercular peritonitis in early life which have occurred at the Infants' Hospital and at the Children's Hospital during the last eighteen years, and a table of these cases will be given later.

The symptoms in infancy and early childhood of tuberculosis of the peritoneum are so varied, unsatisfactory and obscure that it is of great importance first to determine whether the case is tubercular or not, and next whether the tuberculosis is of the peritoneum, lung, lymph-nodes or any other part of the economy.

In many cases the physical examination fails to give us this knowledge, and if the temperature is irregular and much raised, as 102, 103 or 104, it will often be impossible to determine this question decisively. If, however, the temperature is moderate, 99 to 100 or 101, and keeps fairly regular within these bounds, we can with decided benefit use the tuberculin test. Although it can not at present be said that a tuberculin reaction will take place in every case of tuberculosis in infants and children, yet it is of value when it occurs, although its negative evidence is not decisive.

After having made ourselves fairly sure that tuberculosis is present, it should next be decided, if possible, whether the tuberculosis exists elsewhere than in the abdominal cavity. This in early life is often exceedingly difficult, as there may be a tubercular process in the thoracic cavity, either of the bronchial lymph-nodes or of the lung itself, without physical evidence, the sputum

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. H. M. McClanahan, Edwin Rosenthal and Samuel W. Kelley.

in these cases often being impossible to obtain. A swab, however, for culture should be taken from the esophagus, and will in some cases reveal the presence of the tubercle bacillus, which otherwise would not have been detected. The examination of the blood in reference to leucocytosis is of very little diagnostic value, as leucocytosis may or may not be present.

An examination of the urine for tubercle bacilli should be made in cases where there is evidence of renal or vesical disturbance. All these examinations, when they have failed to give results, are merely negative evidence and are simply to be used as additional factors in the problem which is being solved. If the bacilli are found from the swab, or in the urine, this would be so much evidence in favor of there being tuberculosis in some part of the lung or in the genito-urinary tract in addition to the possible presence of tuberculosis of the peritoneum.

There are certain facts connected with the age of the individual which aid us in making a practical clinical classification, and which are worthy of great consideration.

Tuberculosis of the peritoneum may occur both in infancy and in childhood, but those forms which show a marked inflammatory condition, either with or without ascites, are more common in children than in infants. In infants, on the other hand, it is more common to have a miliary tuberculosis of the peritoneum in the course of a general tuberculosis which does not as a rule show abdominal symptoms. In children, again, the peritoneal inflammation may be so localized as to constitute a disease of itself, and this is so marked that this phase of the disease and this stage of the development of the individual constitutes what, for want of a better name, is called "chronic tubercular peritonitis," and it is this chronic tubercular peritonitis occurring in individuals most frequently from 1½ to 4 years of age which can be treated as a disease per se, and which gives us the largest percentage of recoveries from tubercular peritonitis by means of laparotomy.

We can therefore state that, provided we have a localized tubercular process in the peritoneum which is chronic in its course, that it is this class of cases which should be treated by laparotomy. In this class of cases, however, certain forms give a better prognosis than others. The most favorable form for treatment by laparotomy, is where the first pathological form described above is present, that is, miliary tuberculosis of the peritoneum with ascites; while the less favorable form for laparotomy is that which we have spoken of above as the fibrous form, and the prognosis in this fibrous form seems to be more favorable if ascites is present than if ascites is not present.

Here again I would draw attention to the fact that while in early chilhood after the first year this miliary tuberculosis of the peritoneum is the most favorable form for laparotomy, yet on the other hand laparotomy is seldom of avail during the first year of life, as miliary tuberculosis of the peritoneum in early infancy is usually part of a general tuberculosis and therefore can not be benefited by laparotomy owing to the activity of the tubercular process elsewhere.

Given, then, the opinion in a special case that tuberculosis of the peritoneum is present, we first consider the age in determining whether laparotomy should be performed. If the patient is under one year, although as a last resort we may operate, it does not have the same favorable prognostic significance as at a later period. Moreover, we can expect a more favorable result from laparotomy when ascites is present, as the presence of ascites usually shows a less advanced and more active process than when it is not present, as is often the case in the fibrous form, which has been stated to have a less favorable prognosis.

If by means of physical examination we have made up our minds that we probably have a localized fibrous form to deal with, the opinion being based on the detection of masses large and small in the abdomen, without evidence of fluid, even then it is better to operate than to run the risk of the child dying of exhaustion, provided we find no evidence that tuberculosis exists outside the abdominal cavity.

In the third or so-called ulcerative tuberculosis of the peritoneum it is usually evident on physical examination that there is tuberculosis elsewhere than in the abdominal cavity, the probability being that it is in the bronchial lymph-nodes or lungs, and that the tubercular peritonitis in this instance is secondary to a thoracic tuberculosis, and therefore, as a rule, can not be benefited by laparotomy.

The primary forms, on the contrary, had much better always be operated on, even when the infection is secondary to a tubercular mesenteric lymph-node, for the removal of such node or nodes is indicated and in such cases there is a fair chance for a radical cure of the general tubercular infection of the peritoneum.

I have had cases in which a child who was failing in appetite, losing in weight and strength, and having a heightened temperature, and in whom a tubercular mesenteric lymph-node was detected on physical examination, completely recovered after removal of the tubercular node, and in whom after a number of years, at least five or six, there was no return of the disease.

There have, of course, been cases of tubercular peritonitis which have recovered spontaneously, but the fact that this result can occur does not indicate, as has been suggested by some writers, that we should not operate but should wait and see whether such spontaneous recovery would take place.

The danger of a localized tubercular peritonitis, which we know can get well, becoming disseminated and thus producing a general tuberculosis or a local tuberculosis of the lung or brain, is undoubtedly a great one, and knowing that if this dissemination does take place the child will in all probability die, it seems much more reasonable to operate before such dissemination has taken place than to wait until it is too late. It is also well known that, first, in individual cases of localized tuberculosis we are unable to say whether such cases will recover spontaneously or will become a general tuberculosis, and second, that an exploratory laparotomy, when performed by an expert, is known to be of little danger, especially in the earlier stages of the disease when the child has not yet become markedly reduced in strength and vitality.

Is it not better, then, to give the child the benefit of the chance, and when we are reasonably sure that tubercular peritonitis is present in a child over one year of age, and when there are no evident signs of tuberculosis elsewhere, or possibly only in the mesenteric lymph-nodes, is it not better to make an exploratory laparotomy at once?

At a meeting of the American Pediatric Society, held in Boston on May 27, 1902, I presented[1] 6 cases of tubercular peritonitis in which laparotomy had been performed and complete recovery had taken place. These

1. Reviewed in THE JOURNAL A. M. A., Oct. 18, 1902, ¶70, p. 1009.

cases were only 6 out of the 20 cases which have been operated on and recovered in our service at the Children's Hospital. [The other 18 cases lived at too great a distance to be brought to Boston.] I also found in our service at the Infants' Hospital during the same period only one case of tubercular peritonitis. This case died, and proved to be one in which the tubercular peritonitis was part of a general tuberculosis, thus exemplifying what I have already said, that tubercular peritonitis in the first year of life is rare as a primary disease, and is almost invariably part of a general tuberculosis.

I wish to acknowledge the courtesy of my colleagues at the Children's Hospital for allowing me to report those cases which happened to occur in their respective services.

During a period of 18 years, from 1884 to 1902, the total number of cases admitted to the Children's Hospital in which the diagnosis of tubercular peritonitis seemed reasonably certain was 69. Of this number 39 were boys and 30 were girls.

The relative occurrence at the different ages showed the condition to be extremely rare in the early months of life, the youngest case recorded being 14 months. After the first year and a half of life the disease was found to become frequent and was most common between 2 and 4 years, after which it was of only occasional occurrence. The influence of age to the disease is seen in the following table: One to 2 years, 11 cases; 2 to 3 years, 17 cases; 3 to 4 years, 14 cases; 4 to 5 years, 9 cases; 5 to 6 years, 4 cases; 6 to 7 years, 3 cases; 7 to 8 years, 1 case; 8 to 9 years, 5 cases; 9 to 10 years, 1 case; 10 to 12 years, 4 cases.

The average duration of the symptoms before the child entered the hospital was about three months. The statements made by the mother were often indefinite. Usually the first thing noticed was the gradual and increasing distention of the abdomen, which was present in nearly every case except those which began as tubercular meningitis. Occasionally the swelling appeared to come on quite acutely, sometimes following a blow or fall, and at times rapidly increased. The course was usually chronic, sometimes dating back a year or even more, and associated with failing health and loss of weight. In many cases rhachitis is mentioned as being present, but the hospital records were not sufficiently explicit on this point to be of much value. Distention of the abdominal veins was recorded in 3 cases only.

FAMILY HISTORY.

There was a family history of tuberculosis in 20 cases, representing 30 per cent. This, however, bears no relation so far as the statistics are concerned to the death rate.

GENERAL SYMPTOMS.

Abdominal tenderness was generally absent, and if present was rarely severe. The movements of the bowels, so far as recorded, were not significant, loose movements and constipation alternating, and one being about as frequent as the other. Even in the cases in which an autopsy subsequently showed the presence of tubercular ulcers of the intestines, there was, as a rule, nothing especially characteristic or suggestive noted in the discharges.

SPECIAL SYMPTOMS.

The temperature was irregular and, as a rule, elevated, although in some cases it was only slightly above normal, and at times was normal or even subnormal.

The pulse was usually accelerated, its rate varying between wide limits.

The respirations also were generally accelerated, and varied between wide limits.

There were records of white blood counts in only 23 of the 69 cases. These counts showed an average leucocytosis of 16,435, the lowest count being 5,400, the highest 44,000. Counts of 15,000 to 20,000 were frequent. In certain of the cases, but by no means in all, the leucocytosis could be explained by coexisting inflammatory changes. So far as this series of cases is concerned, we must admit that the presence or absence of leucocytosis is of very little value in either the diagnosis or the prognosis of tubercular peritonitis in children.

An analysis of this series of 69 cases in reference to the mortality gives the following result:

In Series 1, number of cases dying in the hospital, without operation, 20, or 29 per cent.; after operation, 12; total number of deaths occurring in the hospital 32, or 46.3 per cent.

In Series 4, total number of cases discharged without operation, 17, or 24.7 per cent.

Of the 32 cases operated on the results were:

In Series 3, recovering from operation and discharged to parents, 20, or 62.5 per cent.

In Series 2, dying in the hospital after operation, 12, or 37.5 per cent.

In the analysis of the four series of cases, into which the 69 cases are naturally divided, I have made use of the following signs:

* = Cases in which autopsies were obtained.

+ = Definitely stated to be present, or reasonably inferred to be present from the data given in the records.

+? = Not definitely stated to be present, but probably present by inference.

? = Data not sufficient to justify one in affirming or denying the point in question.

0 = Definitely stated to be absent or negative.

— = Not definitely stated to be absent or negative, but presumably absent.

The Arabic numerals are the numbers of the cases.

1. Complicated by diphtheria (?).

Of the cases in Series 1 autopsies were obtained in 18, in which not one showed the lesions of tuberculosis to be limited to the peritoneum and mesenteric lymph nodes. Eleven cases showed tuberculous ulcers of the intestines, but their presence could not have been diagnosticated from the clinical symptoms recorded. Seventeen cases showed some tuberculous lesions of the lungs. Twelve cases showed tuberculous lesions of the brain or meninges.

SERIES 2.—Cases Dying in the Hospital After Operation.

2. Complicated with general septic peritonitis and intestinal perforation.

Six of the 12 cases of Series 2 (i. e., 16, 19, 47, 51, 56, 69) were on incision of the abdominal wall found to be practically inoperable, owing to the extensive adhesions of the intestines to each other and to the abdominal wall. Four of the above-mentioned cases had fluid in addition to the adhesions.

3. Discharged not relieved. Incision abdominal wall. Further operation made impossible by universal intestinal adhesions.
4. Complicated with ovarian cyst.
5. Relieved, recurrence. Discharged because of pertussis.

SUMMARY.

A summary of the cases in Series 3 shows that the condition when discharged was the same or worse in 5 cases, or 25 per cent. In 4 (Nos. 13, 42, 63, 66) of the 5 cases intestinal adhesions prevented successful operation, although in 2 cases some fluid was present. Extensive adhesions, therefore, are shown by this limited number of cases to be a distinctly unfavorable condition. The condition in the remaining case was not stated at the time of its discharge. That is, of the 5 cases operated on in Series 1, 2 and 3 in 5 per cent. it was impossible to learn what the condition was at the time of the child's discharge.

A limited number of adhesions did not apparently affect the results of the operation, as they were present in six of the fourteen satisfactory results. The report of the operation in a number of cases failed to give information as to the extent of the adhesions found at the operation. Satisfactory results were obtained in cases numbered 9, 10, 44, 48, in which no fluid was present. Therefore, the absence of fluid does not preclude an immediately successful result.

The presence of fluid with few or no adhesions, and with the absence of tuberculosis elsewhere would seem to be the most favorable class of cases for operation.

The analysis of these 69 cases, therefore, shows that tuberculosis of the mesenteric lymph-nodes does not preclude a successful result. Also, that inasmuch as the presence of palpable masses and the absence of fluid does not preclude a successful operation, and inasmuch as the degree of intestinal adhesions can only be surmised before operation, laparotomy would seem to be indicated in all cases of tubercular peritonitis, provided (1) that the general condition of the patient permits it, and (2) that there is an absence of evidence of cerebral, pulmonary or extensive glandular or bone tuberculosis.

The presence of tuberculous ulcers of the intestines is obviously an unfavorable condition for operation, but in many cases they cannot be diagnosticated by the clinical symptoms.

Of the above 20 cases operated on and discharged relieved, 13 have been traced and the results known up to the present date, June, 1902. Of these 13 cases 11 are to-day well, 2 have died and one is undergoing a relapse. The final results of the operations to date may be seen in the following table:

Case 5 died 7 months after operation.
Case 9 is well 2 years after operation.
Case 10 is well 2 years after operation.
Case 13 is well 4 years after operation.
Case 20 is well 5 years after operation.
Case 37 is well 9 years after operation.
Case 44 was well for one year, but is now undergoing a relapse.
Case 49 is well 3 months after operation.
Case 52 is well 2 years after operation.
Case 59 is well 3 years after operation.
Case 60 is well 2 years after operation.
Case 66 died 4 months after operation.
Case 67 is well 3 months after operation.

Of these 13 cases, which ultimately recovered, 2 (Nos. 13 and 66) were in poor condition when discharged.

Of the 7 cases, the ultimate results of which we could not trace, all but 2 were in excellent condition when discharged, and inferentially were permanently benefited by laparotomy.

SERIES 4.—Cases Discharged from Hospital Without Operation and Against Advice.

Number of Case.	1	2	4	12	17	18	21	27	30	31	32	34	36	53	54	62	64
1. Presence of fluid	+	+	?	+	?	+	0	0	?	+	0	0	0	?	0	0	0
2. Abdominal distention	+	+	0	+	+	+	+	+	+	+	+	+	+	+	+	+	+
3. Palpable masses in the abdomen	.	+	+	−	−	−	+	−	+	+	+	?	+	+	+?	−	−
4. Enlarged lymph nodes neck, axillæ or groin	−	−	+	−	+	+	+	−	−	−	−	+	−	−	−	+	+
5. Probable tuberculosis elsewhere	.	?	?	?	6 +?	6 +?	? ?	? +?	6? ?	?	?	9 +?	7 +?	8? 8?	−	8? +?	?

7. Condition at discharge	Slightly relieved.	Relieved.	?	Improved.													

6. Lungs. 7. Lung. 8. Kidney. 9. Ankle.

In this series there were 17 cases, in 10 of which there was more or less evidence of tuberculosis elsewhere. Eight cases (Nos. 1, 2, 4, 12, 31, 32, 34, 64) were operable, and of these 8, 4 refused operation. In the remaining 9 cases there were strong indications against operation.

Of these 17 cases 9 were discharged relieved, but the data as to the exact condition of the patient when discharged is not satisfactorily stated.

Of the above series only 5 could be traced, and of these all are alive (Nos. 12, 17, 32, 53 and 64).

Before ending this paper I wish to recognize the laborious and exact work done by Dr. Maynard Ladd,

who has carefully gone over the records of all these series of cases and arranged them as I have presented them to you.

DISCUSSION.

DR. J. M. DODSON, Chicago—A point of interest is the use of tuberculin for diagnostic purposes, not only in tubercular peritonitis, but in suspected tuberculosis of the lymph nodes. There is, fortunately, a reaction from the disappointment experienced in the early history of the use of this agent. Its immense value and perfect safety when used under proper conditions are now beginning to be recognized. In a condition like tubercular peritonitis, where the diagnosis is often so obscure, its great value is, of course, evident.

There is another remedial measure which holds out, it seems to me, some promise, i. e., the use of the *x*-ray. In a number of cases of tubercular peritonitis in adults in the Presbyterian Hospital in Chicago, the *x*-ray has been used with very gratifying results. There has been a subsidence of tenderness and pain, and a disappearance of the effusion and of the fever. It is too early to say whether the relief will be permanent or not. Theoretically, we have much reason to hope that the *x*-ray may prove of use in the more deeply-seated tubercular affections. By whatever means it may produce its effects in cutaneous tuberculosis or lupus, the good it has done can not be denied. It is a remedy, moreover, which, with the more recent apparatus and methods, can be employed with safety, and utilized in children and even in infants with safety, if care is taken as to exposure and adjustment of the apparatus. I would, therefore, suggest the use of the *x*-ray, especially in those cases in which operation is contraindicated.

DR. MARGARET T. SHUTT, Springfield, Ill.—I was engaged some time ago in making blood counts in a child. There was a leucocytosis of 30,000 in addition to a marked anemia. It was a rather acute condition, and there was present a tumor on the right side. The diagnosis was in doubt because of the regularity and size of the tumor, until at operation it was found that the tumor was composed of matted intestines and omentum and large tubercles. It was supposed, because of the size of the tubercles, that no good would result from the operation, but when I last heard of the child, about twelve months later, it was apparently perfectly well. In another recent case of miliary tuberculosis in a child of ten I made a blood count, and found no leucocytosis, but a marked anemia. That case has not yet been operated on.

A CASE OF PROGRESSIVE IDIOPATHIC ATROPHY OF THE SKIN.*

A. RAVOGLI, M.D.

CINCINNATI.

Progressive atrophy of the skin is an affection of great importance on account of the causes producing it and the conclusions which we can derive therefrom. Cases of this affection have been reported by Buchwald, Touton, Colombini, Elliott, Bronson, Pospelow, Neuman, Ohmann-Dumesnil, Popoff, Jadassohn, Unna, Krzysztalowicz and others. In some of the cases the morbid process producing atrophy of the skin was known, in others it was perfectly obscure. From the study of all the reported cases Unna gave his classification of the atrophies of the skin as idiopathic and deuteropathic, calling idiopathic the cases where the skin is primarily affected, without progressed morbid process, and deuteropathic the cases of atrophy where the skin falls into atrophy secondarily on account of a tubercular, syphilitic or other process which has damaged its stroma.

Our case belongs to the first group, the affection occurring primarily on the skin. The idiopathic atrophies are also distinguished as limited and diffused, and our case belongs to the second. Although in general the causes of the atrophy of the skin are obscure, yet the authors unanimously agree that the atrophy of the skin is the consequence of a disturbance of the innervation. The affection of the nervous system in these cases has a disturbing influence on the trophic nerves, and the skin in consequence falls in an atrophic condition. Before proceeding to the study of the action of the trophic nerves and to the cause of their disturbance, it is better to call our attention to the results of the atrophic process on the tissues of the affected skin, to be able to find out the pathologic alteration, which may clear up somewhat the process from which they are derived.

The case under consideration is of more interest because an autopsy could be held.

Flora F., 18 years of age, was admitted into the city hospital under the neurologic service, and I thank Dr. Hoppe for permission to use the history of the case. She was brought to my attention on account of the peculiar condition of her skin.

Her mother is living and is a strong woman in good health. Her father died some years ago, they claim from consumption.

Personal History.—The patient was four feet and ten inches tall, of poor and meager development. Three years ago she claimed to have had typhoid fever, and from that time she discovered the atrophic condition of the skin. She has always been a weak and delicate girl; she attended school, but stopped, as the work was too hard for her. She often had fainting spells. Lately her condition grew worse, she got dizzy and fell without losing consciousness. She could not walk without help, had an ataxic gait, and was constantly leaning on the left side. If the support was taken away from her she fell toward the left.

Examination.—From the photograph it appears that she had a mask-like countenance, the eyes large and staring, bulging and expressionless; both pupils were dilated, but the right more so; the left eye was somewhat convergent; the pupils did not respond to the light.

With the ophthalmoscopic examination was found edema of the optic disc, with some exudation around spreading to the retina for a short distance. The veins were swollen and tortuous, the arteries reduced in size, the same in both eyes. From the ophthalmoscopic finding was made the diagnosis of double, optic neuritis. The external rectus of the left side was paralyzed. At times she suffered with headache. Her grip was very weak, the knee-jerk exaggerated on both sides, no ankle clonus. Plantar flexion bilateral.

Her skin was somewhat white and anemic all over the body, but thin and soft. It showed white superficial scars, like patches, which reminded one of the appearance of mussed cigarette paper (Pospelow), thin and atrophic. One round scar the size of a five-cent piece was one inch above the left eye, and another on the left side of the forehead at the hair line. The largest scar occupied in a semicircular course the right side of the chest, beginning at the jugular region, running down to the right breast one and one-half inches below the nipple, from there around the axilla of the same side covering the whole shoulder to the apex of the scapula, then extended to the whole right arm and forearm, stopping at the wrist. On the left arm a circular scar of the same character was on the elbow, on its extension surface, five inches in length. Another large round scar was seated on the internal surface of the left thigh, oval in shape, seven inches in length. Two other round scars were on both knees on the extension surface.

All the cicatricial areas had a peculiar dull pearl-white color, glistening in places, smooth in others, showing small holes or indentations as if honeycombed, or small cicatricial string-like elongations. It could not easily be raised in folds and when raised remained folded for a while, like parchment paper. The whole cicatricial surface did not show the underlying blood vessels; it seemed destitute of pigment, lanugo hair could not be found, no desquamation was ever seen. On the periphery of the affected skin round, reddish-brown erythe-

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. W. T. Corlett, L. Duncan Bulkley and W. L. Baum.

matous spots were found, which lasted only a few days, leaving the skin in the already described condition.

In the atrophic skin of the arm a yellowish-green patch, result of a contusion, was observed, which the patient referred to a fall on her arm in attempting to walk. She felt no pain on the affected skin and would have scarcely noticed it except for its appearance. The atrophy of the skin began some three years ago at the time when she claimed she had typhoid fever, and progressed gradually to the present condition. The muscles of the affected arm were weak and she could move it with difficulty. The sensibility in the cicatricial areas was somewhat benumbed. Two test tubes, one filled with hot water and the other with ice water, were applied on the scar surface and there was some hesitancy in distinguishing which was the hot and which was the cold. When tried with the head and with the point of a pin, on the cicatricial areas, she could not distinguish them as she did on the normal skin. The sense of pain was still maintained, although somewhat benumbed.

The condition of the patient grew gradually worse, at times she became delirious, at times she fell in a stupor, regaining consciousness again, and died April 26, this year.

Autopsy.—The postmortem was held on the same day by the neuropathologist of the hospital, Dr. David Wolfstein. The limited time does not allow me to give a full report of the alterations which were found in the different organs. I will only mention that in the liver were found deep cicatrices, extending to the parenchyma, and also some grayish-pink nodules around its surface. The spleen was greatly enlarged, swollen, friable and congested. The interesting alterations were all in the brain. Dura normal, pia mater showed a fibrous thickening near the longitudinal fissure. Under the right frontal lobe in the orbital surface a gumma was found the size of a walnut, and in the same place in the median line a small-sized gumma confined to the gray matter. Another gumma was found in the right caudate nucleus extending back to the internal capsule. A large gumma was found in the temperosphenoidal lobe, which showed a marked area of softening. On the base of the brain the third nerve was covered with a gelatinous translucent mass, but the nerve appeared healthy. Some gelatinous mass was collected on the upper part of the right optic tract pressing on the right middle cerebral artery. Some infiltration was marked on the right surface at the junction of pons and medulla. Imbedded in this mass was the right sixth nerve, the basilar and the cerebral artery, the seventh and eighth nerves. On the left side another gummatous production was found on the exit of the fifth nerve, and in the middle pedicle of the cerebellum. Spinal cord was normal.

The report of the pathologic alterations which were found especially on the base of the brain show the interesting rôle of the nervous system in the nutrition of the tissues and consequently the production of the atrophy of the skin.

The experiments begun by Claude Bernard, continued by Ludwig, Thicq, Owsjannikow and Dittmar have established the presence of a vasomotor center, which is placed at the point of the calamus scriptorius, extending to the corpus trapezoides as a place very rich in multipolar gangliar cells. Any irritation produced on this point causes the constriction of the arteries of the whole body, and in consequence increasing of the blood pressure. And, on the contrary, a cause producing paralysis of this center causes dilatation of all arteries and consequent diminution of the blood pressure. The gangliar cells which are in the fourth ventricle, according to Onuf and Collins, originate sympathetic fibers. From this vasomotor center the vasomotor fibers proceed together with motor and sensitive fibers through the internal capsule toward the pons to the center of the vasomotor nerves, the medulla oblongata.

In this case it is clear that the pressure produced over the cells of the vasomotor nerves has been the cause of the atrophy of the skin. Weir Mitchell found that on cutting the nerves through the perspiration and the secretion of the sebaceous matter of the skin stopped entirely, while on cutting the nerves partially the secretion and the perspiration continued, and in some cases a glossy skin appeared. In some cases of traumatic neuritis Cassirer found hyperhydrosis in the corresponding regions where a glossy skin existed and yet the motor and sense functions were maintained.

We can say that the idiopathic atrophy of the skin is in most of the cases the result of a trophoneurotic alteration, which may be the result of an affection of the vasomotor center, as in the present case, or from peripheral affection of the nervous ramifications or of the nervous ganglia. A trophoneurotic affection is constantly accompanied by other alterations of sensibility and also of stasis in the blood vessels.

The influence of the trigeminus in the nutrition of the epidermis was demonstrated by the experiments of Gaub, who found that after cutting this nerve between its origin and the ganglion Gasseri in the epidermis, there were developed necrotic patches, and in other places epidermic growths.

Returning to our patient, she never complained of any pain, and she would have scarcely noticed the affection except for its appearance. It is interesting to recollect that the muscles of the affected arm were weak and the sensibility partially maintained.

During her life I removed a small piece of the affected skin, near the edge of the atrophic patch, which was treated in 4 per cent. formalin solution, hardened in alcohol and stained by different processes.

The course, the clinical symptoms and the pathologic alterations of the skin show that the affection is the result of an inflammatory process of a trophoneurotic origin, which soon causes atrophy and sclerotic condition of the tissues of the skin. In my specimens I was able to find a discrete small cell infiltration in the layers of the derma in the papilla and surrounding the glands, as was found by Buchwald, Jadassohn, Colombini and also between the collagenous fibers as found by Neuman. Unna and Huber found the plasma cells, which I could find in my specimens, together with enlarged connective tissue corpuscles between the collagenous fibers. The superficial layer of the derma is the place where the infiltration is found most abundant. The connective tissue fascicles as noted by Krzysztalowicz are thickened and hypertrophic; they run like waves, reminding one of the structure and disposition of the fibers in keloid. The same thickened condition of the fibers can be seen in the flattened papillæ, where I could find some large cells in a hyalin degeneration. The elastic fibers seem to be somewhat diminished, and this observation is confirmed by those of Heuss and others who have found them in an atrophic condition. In some places the papillæ are flattened, in others elongated and in a triangular shape.

The epidermis is greatly changed, the stratum corneum in some places is much thinner on account of the flattening of the epidermic cells, which form a kind of dry thin lamellæ. But in some places it is somewhat thickened, as can be seen in Figure 1, and as was found in the case described by Pospelow. Neuman in his case described the horny layer as a strip without nuclei, the stratum granulosum reduced to a simple row of cells, the stratum spinosum as fairly maintained. Colombini described the horny layer very much thinner with flat dry cells, the stratum granulosum resulting of only one row of cells, the stratum spinosum atrophic,

and the basal layer formed by small cells filled with pigment. Huber found the horny layer thinner, the stratum granulosum formed by only one row of cells and the stratum spinosum greatly reduced in thickness, consisting of elongated cells with small nuclei, so, too, the cells of the basal layer were smaller and filled with pigment granules. Unna, in his description and in his microscopic illustrations, showed the horny layer unequally thickened, the stratum granulosum sufficiently preserved, but the stratum spinosum atrophic, and the columns of cells are no longer found between the papillæ. The description given by Krzysztalowicz is entirely in accordance with that given by Unna. In Figure 2 can be seen the stratum corneum much thinner, consisting of dry lamellæ where nuclei can not be seen; the stratum lucidum has disappeared, pigment in a very small quantity can be found. The stratum granulosum is reduced to one row of cells, while the stratum spinosum shows the cells well maintained but elongated horizontally, having lost their cylindrical appearance and somewhat disarranged. The whole epidermic surface appears uneven and irregular.

The papillary layer seems to be the part mostly affected of the atrophic skin; in some places the papillæ have completely disappeared, in others they are enlarged

Figure 1.

Figure 2.

and of an irregular shape. The papilla appears to be made up of a thick fibrillary substance, which does not react as elastic, but more as a collagenous substance. In some the blood vessels are enlarged and a scanty accumulation of cells can be seen in their composition. Enlarged connective tissue corpuscles are also crowded into the papilla. The fascicles of the fibers forming the stroma of the corion are thicker and crowded together, and are sufficiently stained with orcein and with acid fuchsin, without showing a distinct appearance. The fibrillæ are enlarged and have a kind of wave-like disposition, which reminds one of the structure of the keloid.

Buchwald had already pointed out a swelling of the subepidermic layers, and indeed it seems to me that in this place occur the most important pathologic changes. The fascicles of the fibrillæ of the papillary layer are changed into homogeneous, collagenous fibers. The degenerative changes of these fibrillæ are well demonstrated by Figure 3, a microphotograph from a specimen treated with orcein, polychrome and washed in glycerin and ether, which shows the nuclei and a kind of granoplasma contents of the collagenous tissues (*b*). In this specimen can be seen quite abundant plasma cells (*a*), to the presence of which Unna and Huber have called attention. The infiltration and the plasma cells are more often found around the blood vessels in their adventitia. Multinuclear leucocytes were not found by Krzysztalowicz, and the small infiltrating cells are found (*c*) around the small blood vessels and also between the collagenous fascicles.

In my specimens the blood vessels of the superficial layer of the corion are enlarged, with a thick infiltration around their adventitia and with a swollen endothelium, which is in accordance with the observations of Heller and Huber. Unna states that he found blood vessels enlarged but nearly obliterated on account of a shrinking of their lumen. The sweat glands appear smaller and in an atrophic condition. They are in a horizontal direction, and their excretory ducts can not be seen. I did not find in my specimens follicles of the hair or sebaceous glands. Unna has found the flat muscles of the skin smaller and in atrophic condition; in my specimens also the muscles arrectores pilorum can be seen, but not distinctly. Their condition is subordinate to the degree and to the intensity of the atrophic process of the skin.

In regard to the elastic fibers nearly all authors maintain that they are in an atrophic condition. Colombini pointed out that the elastic fibers in regard to their form, thickness and number were in a regressive proportion, and their atrophy was much more perceptible in the papillary and in the superficial layer of the corion than in the deeper strata. Huber has found a diminution of the elastic fibers in the places showing infiltration. Unna refers to the atrophy of the elastic fibers as a diffuse and irregular one; that they have lost their fibrillary appearance, and that they are thinner and are very weakly stained. I can only confirm the observations referred to, as in our specimens the elastic fibers show very little of their presence, and the whole structure of the corion seems to be made up by abundant, thick and enlarged collagenous fibers.

In some places in the subepidermic layer granules of pigment are found, while no pigment was found in the basal layer of the epidermis.

In regard to the lymphatic spaces, Colombini and Buchwald claim that they are abnormally enlarged. Pospelow claims to have found them normal. Unna has found the lymph spaces nearly normal in the superficial layer of the corion, and greatly enlarged in the deeper layer. In what concerns the nervous system Unna stated that he, like the rest of all authors, has never found any abnormal condition of the nerves. In some of my specimens the nervous ramifications are clearly

perceptible, but they are compressed in a quantity of thick and hard collagenous fibers. In a deformed and enlarged papilla I have found a nerve entering a corpuscle, compressed by the crowding of the thick collagenous fibers. The neurilemma is thickened and the nervous body is elongated and distorted. The cylinder axis is turbid and the nerve fibers are not easily perceptible. The membrane which forms the nervous corpuscle is thickened and covered with infiltrating cells.

The question now is, whether the atrophy of the nervous corpuscles is the consequence of the compression of hardened collagenous tissues on the nervous ramifications, or whether the atrophic condition causes disorders of nutrition in the tissues of the skin, with the resulting pathologic alterations.

We have cases of progressive atrophy of the skin in healthy persons, limited to one part of the body which is supplied by an affected nerve. In these cases the origin of the nervous affection is not from the central organs, but is limited to one, or to one group of peripheral nerves. In one case I have under treatment, of which I show the photograph, the atrophy of the skin took two years to invade the internal surface of the arm and the flexion surface of the forearm, and the affection has been accompanied by intermittent neuralgic pains

Figure 3.

of the brachial plexus. It was nothing else than a case of peripheral neuritis, which caused the atrophic condition of the skin, with a remarkable effusion of the coloring matter of the blood and consequent pigmentation.

The disturbance of the trophic nerves causes hyperemia of the small arteries and stasis of the veins; from this an effusion of serum and of small leucocytes occurs in the tissues and an increased nutrition starts the proliferation of the connective tissue corpuscles. The anomalous hypernutrition causes the hypertrophy of the fascicles of the fibers and gradually their collagenous condition. The thickened and hardened collagenous fibers pressing on the delicate elastic fibers cause their atrophy. The papillæ have disappeared or are atrophic. The nervous terminations, Meissner and Pacinian corpuscles are also atrophied, which explains the benumbing of the sensibility and the alteration of the nutrition of the epidermis. The epidermis derives the nutrition from the papillary layer, which when in an abnormal condition will afford only an abnormal nutrition. For this reason we have seen the epidermic layer compressed and irregularly developed, the excretory ducts of the glands obliterated, the hair and the sebaceous glands disappeared. The pathologic alterations of the epidermis are not the cause of the sclerotic condition of the derma, as Krzysztalowicz is inclined to maintain, but are only the consequence.

Pospelow, Jadassohn, Neuman and Huber refer this affection as a result of trophoneurotic disturbances, and Neuman calls the process "lenticscierenden trophoneurotischen Entzündungs Process." The result of the autopsy of our case upholds the opinion of Neuman, showing the diffuse progressive atrophy of the skin to be the result of the presence of a syphilitic gumma on the junction of the pons and of the medulla pressing on the origin of the seventh and eighth nerves, just at the point which is the center of the vasomotor nerves. That the process is of a chronic inflammatory nature is clearly shown by the clinical symptoms and by the pathologic alterations. The end of the process is the atrophy, which is the consequence of a sclerotic process, the end of the evolution of the chronic trophoneurotic inflammation.

Although we know that this atrophic condition of the skin is the result of an inflammatory process caused by the irritation or the paralysis of the vasomotor center, yet the name of idiopathic must remain, as it occurs primarily in the tissues of the skin without any other progressed process. In this way this atrophy is distinguished from other forms which have been called deuteropathic by Unna, where the sclerosis and the atrophy of the skin is a true cicatrix, the result of an infectious inflammatory process such as the tubercular or syphilitic, which has damaged the stroma of the skin.

The case referred to belongs to the class of skin atrophies which Unna has grouped as those resulting from nervous diseases. Their prognosis is entirely subordinate to the extension and nature of the affection of the nervous system, which in many cases is of such character that therapy does not afford any means of relief.

DISCUSSION.

DR. W. T. CORLETT, Cleveland—I have seen cases of atrophy of the skin, but never such an extensive case as has been detailed by Dr. Ravogli. Moreover, it is very seldom one gets an opportunity to hold a postmortem examination. Such cases often pass out of the observation of dermatologists, and when death finally occurs the disease may not even be interesting or at all understood by the medical attendant.

DR. W. S. GOTTHEIL, New York—I desire to show some photographs in this connection illustrating a case of progressive idiopathic atrophy, which Dr. Abrahams had intended to exhibit at this meeting. It is a very marked case, involving the

entire skin of both lower limbs up to the middle of the buttocks. The immediately interesting point is the upper advancing margin of the disease, which is erythematous, distinctly inflammatory and tender. As you are well aware, the main point of discussion in connection with this entirely intractable disease has been in regard to its being inflammatory or not in its beginnings. The microscopic findings have been at variance. This case has been distinctly inflammatory along its advancing margins from the very beginning. This settles the question, so far as clinical observation can do so, in certain cases at all events. We propose at a future time to publish the case, and detail the results of the microscopic examination of the skin at the advancing margins.

THE RELATION OF LUPUS ERYTHEMATOSUS TO TUBERCULOSIS.*

HENRY G. ANTHONY, M.D.

PROFESSOR OF SKIN AND VENEREAL DISEASES, CHICAGO POLICLINIC.
CHICAGO.

The relation of lupus erythematosus to tuberculosis has long been the subject of a discussion, the final settlement of which we can hardly look for at the present state of our knowledge.

Until more is known of the eruptions which are in some way allied to tuberculosis and which, provisionally, are said to be due to tubercular toxins, and until we obtain more accurate knowledge regarding the cause of lupus erythematosus, our discussions must be of a purely clinical character.

Clinical discussion, although not conclusive, is nevertheless of value, as it eliminates from the controversy many mooted questions, and it renders clinical observation more keen and accurate.

OPINIONS OF VARIOUS WRITERS.

Those who believe that lupus erythematosus is a manifestation of tuberculosis are mostly members of the French school of dermatology. They state that a careful analysis of the family history and a thorough examination of patients will reveal the presence of tuberculosis in most cases.

I have carefully studied the family histories of the cases which have passed under my observation, tracing the history of each and every member of the family, and I have examined my patients for evidences of tuberculosis time and time again, with negative results in the typical cases. I therefore can not recognize the correctness of this assertion.

Kaposi has seen lupus erythematosus in a child of three years, but never in an old person. Besnier[1] says that the reason for this is that these patients die of tuberculosis at an early age, and that they are more apt to succumb to tuberculosis than are cases of lupus vulgaris. Besnier is not entirely right on this point, inasmuch as there are a number of cases on record in which the disease has been observed between the sixtieth and seventieth year of life. Fordyce[2] has reported one case, 70 years of age, where the disease had existed 20 years, and Bronson[3] has reported a case of 93 years.

I believe we lose sight of these patients in many instances, not because they die of tuberculosis, but because, after consulting one physician after another, they give up all hope of being cured and discontinue treatment.

THE AUTHOR'S BELIEF.

Following the leadership of Robinson,[4] I believe that typical discoid lupus erythematosus of the face is a local skin disease, coming under the general classification granulomata, and having nothing whatever to do with tuberculosis.

The reason that the correctness of Robinson's position on this subject is not generally accepted is, in my opinion, due to the fact that those who believe that lupus erythematosus is a manifestation of tuberculosis do not sufficiently separate the typical discoid form of the face from other varieties.

For the purpose of studying the tubercular question here involved, we would exclude all cases of acute lupus erythematosus, all atypical cases, all cases of folliclis* and all cases of lupus erythematosus disseminatus.

NARRATION OF TWO CASES.

A few years ago a patient, aged 40, consulted me for alopecia areata, which had developed during the preceding two months. He was a politician, and had just been through a heated political campaign. The areas of alopecia were four in number. They were each the size of a quarter of a dollar, and of oval form. There was no redness or scaliness of the surface. In the older of these plaques there was a central depressed atrophic scar, which caused me to make the probable diagnosis lupus erythematosus of the scalp. The patient's pulse was 90; the temperature was normal. Examination of the lungs negative. He had no cough or expectoration, and no eruption on any other part of the body. He was advised to take a complete rest, which he did. Three weeks later, on his return to the city, he was again examined. His pulse was still 90; he had a little evening temperature, and we detected râles in the apex of one lung. He was referred to a specialist on lung diseases, who confirmed our diagnosis of tuberculosis of the apex of the right lung. The patient was sent to California, where he died of tuberculosis within a year.

Lilienthal[5] has reported the following case: The patient is 46 years old; previously healthy. Six months ago an eruption appeared on the ear, and later spread to the face, scalp and under extremities, accompanied by fever and rapid emaciation. On the nose is a plaque, with no scaliness; in the scalp are areas of alopecia with atrophy of the hairs. On the fingers are typical lesions of lupus erythematosus disseminatus. At first there was no evidence of tuberculosis of the lungs, but after a time the patient took cold, and on his recovery from this the apex of one lung was found to be infiltrated, and a new eruption of the disease occurred on the back.

THE BASIS OF THE TUBERCULAR THEORY.

It is possible that toxins of tuberculosis cause alopecia with atrophy, just as toxins of syphilis, typhoid fever and puerperal fever cause alopecia without atrophy.

Cases like these, in which a rapidly developing tuberculosis follows the first manifestations of lupus erythematosus, have been reported by many observers, and they impress everyone as being cases in which the lupus erythematosus is a manifestation of tuberculosis rather than the accidental presence of two diseases in the same individual. It is the observation of these cases which forms the basis of the tubercular theory.

They have nothing whatsoever to do with the granuloma lupus erythematosus, although in many instances they cannot be separated from the granuloma. They are, in my opinion, cases of folliclis, that is, eruptions which are in some way related to tuberculosis, without showing, up to the present time, the presence of the tubercle bacillus or the structure of the tubercle.

Erythema multiforme is to-day regarded by many as being both an acute infectious disease and also a symptomatic eruption. I believe the same is true of lupus erythematosus. There is a disease, lupus erythematosus, *sui generis,* and also a symptomatic eruption related in some way to tuberculosis.

Brocq[6] believes that most cases of lupus erythematosus

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. W. T. Corlett, L. Duncan Bulkley and W. L. Baum.

* The word folliclis is a French term which was first applied to these eruptions by Barthelmy in 1891. It has many synonyms.

are due to tuberculosis, but that some cases are due to other causes. Roth[7] states that H. Hebra and Jemieson hold that the disease is caused by different etiologic factors. Hardaway[8] believes that the disease is due to more than one cause, and Galloway[9] says tuberculosis is only one cause of the disease.

THIS DISEASE SIMULATES OTHERS.

Crocker[10] is right in saying that lupus erythematosus is a great imitator of other diseases. There is, however, no class of cases which it so closely imitates as those eruptions which are in some way related to tuberculosis, and which many believe are due to tubercular toxins.

Nobl[11] says that lupus erythematosus disseminatus is the same as folliclis. Were this invariably the rule the division of the cases would be extremely simple—the disseminate form would be tuberculosis, and the discoid form would be the granuloma. The difficulty, in my judgment, lies in the fact that the granuloma may produce a disseminate eruption and folliclis may produce the discoid form; hence, in many instances, it is impossible to separate the two forms, but even at the present state of our knowledge I believe that the two forms may sometimes be differentiated.

Lilienthal states that, in 1872, Kaposi pointed out the fact that when pulmonary manifestations appear the disease quickly spreads, and that, in 1893, Veiel said that the disseminate form was certainly tubercular, and that he found tuberculosis in one-third of his cases of this variety.

Another point of importance in the differential diagnosis is the fact that a study of the tubercular cases shows that they are made up of plaques, one or two of which are typical, and the remaining are atypical.

Inasmuch as folliclis so closely resembles lupus erythematosus and inasmuch as Boeck believes that folliclis is a subdivision of lupus erythematosus, it is necessary to consider certain points which it presents in a study of the relation of lupus erythematosus to tuberculosis.

The present tendency of dermatology is to include the cold abscess, subcutaneous tuberculosis or scrofulotubercular gumma (using these terms synonymously) in the group of folliclis. This, in my opinion, is absolutely incorrect, there is no reason for changing the old classification, "subcutaneous tuberculosis"; in fact, I extend this group, which shows the structure of the tubercle and the presence of the tubercle bacillus and include in it certain cases which are, to-day, classified under other headings.

WHO FIRST DESCRIBED FOLLICLIS.

Toeroek says that the first case of this class of which there is any record is a case reported by Hutchinson in 1879. The second case was reported by Boeck, as a case of lupus erythematosus disseminatus. He sustains the claim of Brocq, that he was the first to describe the disease. These authorities entirely disregard American literature on this subject. It was Duhring, and not Brocq, who first described folliclis under the title, "Small Pustular Scrofuloderm."

My reasons for assigning to Duhring the credit of first describing this disease are as follows: Boeck[13] says that the case which was reported by Bronson in 1891 as a case of acne varioliformis of the extremities was a case of folliclis. Toeroek says it was a case of acnitis of Barthelmy and Dubreuilh believes that both Bronson's case and Pollitzer's case of hydro-adenitis destruens suppurativa belong to the same group as Barthelmy's case. Inasmuch as these authorities believe that hydro-adenitis destruens suppurativa and acnitis are synonyms of folliclis, it will be seen that they agree that Bronson's case was a case of folliclis. In the discussion of Bronson's case Fox[14] spoke of a similar case, shown some time ago, which he had diagnosed acne cachectecorum. Jackson said that the case more closely resembled the pustular scrofuloderm of Duhring. Taylor had seen an eruption similar to this in late syphilis.

As near as can be judged from a description, Jackson is correct in saying that this case is a case of "the small pustular scrofuloderm," first described by Duhring[14 1-2] in 1881. Brocq[15] published his description about 1890, and it corresponds to that of Duhring's as closely as two descriptions independently written ever do.

SITE OF THE ORIGIN OF THE DISEASE.

In two of the cases of folliclis which have been reported (cases of Brocq and Hallopeau), the lesions of folliclis were present on the extremities, and typical lesions of lupus erythematosus were present on the hands.

Dubreuilh, Broeck and Toeroek regard this as the accidental presence of two diseases in the same individual. Toeroek bases his opinion to a great extent on the microscopic findings. He says: "The microscopic findings show, as a difference from lupus erythematosus, the presence of an endophlebitis and thrombosis of the veins on the border of the derma and subcutaneous tissue, as well as a beginning of a necrotic process in the same location in dermatitis nodularis necrotica." He disregards the fact that Gerber and Leloir have stated that lupus erythematosus begins in an alteration of the blood vessels of the papillæ and corium and that Boeck, Holder and Petrini have found thrombi in the vessels.

Pick, the most recent of all writers, says: "Regarding the first appearance of the disease, I agree with Miethke, Schoonheid and others, that the disease begins in the subcapillary vascular layer of the skin. On the border of the lesion we find, first of all, the vessels are dilated and surrounded by a small cell infiltration, which follows the vessels as they ascend into the papillæ."

Hallopeau[16] believes that these cases of a combination of lupus erythematosus and folliclis are different manifestations of the same morbid process, and that they are either cases of abnormal lupus erythematosus, folliclis or new morbid type.

We side with Hallopeau, but we would exclude the new morbid type; were we to believe that these combination cases are abnormal forms of lupus erythematosus, then all folliclis are lupus erythematosus, and that would extend lupus erythematosus *ad infinitum,* and it would be easy to establish a relationship between lupus and tuberculosis by statistics.

If, on the other hand, we believe that tuberculosis may produce both folliclis and symptomatic lupus erythematosus, we have an explanation which is more satisfactory.

Combinations of lupus erythematosus with folliclis, with lupus vulgaris, with rare forms of tuberculosis, with subcutaneous tuberculosis and with pulmonary tuberculosis are, in my opinion, one and all of them cases of tuberculosis, in which one or two patches are lesions of symptomatic lupus erythematosus.

REASONS FOR DIFFERENCE OF OPINION.

With this method of looking at lupus erythematosus in mind, permit me to direct your attention to an article, published by Roth[17] in 1900. He collected from the literature and from the private and clinical practice of Herxheimer, 250 cases of lupus erythematosus, of which 185 cases showed evidences of tuberculosis, and he concludes that there can be no question whatsoever of the relation of the two conditions.

He finds evidences of tuberculosis in 63 per cent. of his cases, which is the highest per cent. yet attained by any observer.

Wherein lies the difference of opinion?

We respectfully submit that the typical cases do not find their way into medical literature, hence statistics founded on reported cases are based, not on the typical, but on the atypical cases.

ROTH'S CLASSIFICATION.

Roth divides his cases into classes. Class A contains 12 cases, reported by Boeck, who states that they are cases of folliclis. As our present knowledge of folliclis is so meager that their exact relationship to tuberculosis is not yet established to the complete satisfaction of many leaders of the profession, and as there are but few who believe that they are in any way related to lupus erythematosus, they should not be employed to bolster up the doctrine that lupus erythematosus is tuberculosis. Class B contains 30 cases of discoid lupus erythematosus in which the glands of the neck were enlarged, also reported by Boeck.

Pick shows that lupus erythematosus may produce an enlargement of the glands of the neck without there being any evidence that the enlargement is due to tuberculosis, and we object to drawing conclusions from the presence of enlargement of the glands of the neck, even where they are tubercular, unless the number of cases observed at the same period of time, in which there was no enlargement, be stated.

Class C contains 81 cases, collected from the literature as reported by various writers. This class consists of a heterogeneous collection of dermatologic curiosities; some of the cases of this class are cases of folliclis, others are cases the diagnosis of which was questioned when they were presented before medical societies. One of them is a case of erysipelas perstans fascei, of Kaposi. They should one and all be excluded from the statistics.

In fact, the only part of Roth's statistics of any value are the cases which he presents from Herxheimer's clinic, of which there are 138 cases, with evidence of tuberculosis in 36, or 26 per cent., as follows: Tuberculosis of the lungs, 9 cases; enlarged glands in the neck, 9; one or more relatives died of tuberculosis, 6; carious bone removed in childhood, 1; glandular scars in the neck, 2; cough and expectoration, 3; tuberculosis of the testicle, 1; lupus erythematosus transformed in lupus vulgaris, 1; previous inflammation of foot, necessitating amputation, 1; reaction to tuberculin, 1; previous symptoms of tuberculosis, 2.

Roth was quickly answered by Dr. Pick[17], of Neisser's clinic, who reported 43 cases of discoid lupus erythematosus, 18 of which, or 43 per cent., showed evidences of tuberculosis, as follows: Tuberculosis of the lungs, 5 cases; relatives died of tuberculosis, 6; enlarged glands in the neck, 6; tuberculosis of the hip joint, 1.

From this it will be seen that the statistics of Herxheimer's clinic show a smaller proportion of tuberculosis than the statistics from Neisser's clinic.

CONCLUSIONS OF THE AUTHOR.

My conclusions are:

1. That discoid lupus erythematosus is a granuloma, which has no relation whatsoever to tuberculosis, but which may be accompanied by a general eruption.

2. That tuberculosis may produce symptomatic lupus erythematosus, usually with disseminate, atypical plaques.

3. That what may be shown by statistics regarding the relation of lupus erythematosus to tuberculosis depends on what is understood as evidence of tuberculosis, and also on what is included in lupus erythematosus.

DISCUSSION.

DR. M. B. HARTZELL, Philadelphia—I wish to ask the writer of the paper what is his authority for asserting that tuberculosis may give rise to symptomatic erythematous lupus.

DR. F. H. MONTGOMERY, Chicago—I think the most of us agree with the writer that ordinary discoid lupus erythematosus is not, as a rule, associated with tuberculosis. There are undoubtedly some exceptions and occasionally a case is seen in which there is apparently a close relation between lupus erythematosus and lupus vulgaris. I remember very distinctly one clinical case which Dr. Hyde and I treated for a number of years for typical lupus erythematosus of the face, scalp, and ears. After disappearing from our observation for a year or two, the patient returned with a typical lupus vulgaris of the nose, producing almost complete destruction of one ala. In a scraping from one of the nodules tubercle bacilli were found.

DR. R. R. CAMPBELL, Chicago—I thoroughly believe lupus erythematosus is not a tubercular disease. And if the statement as made by Dr. Jackson, that it is not an inflammatory disease, can be demonstrated, then I think we will have conclusive evidence that it is not tuberculous, because where we have tuberculosis we have an inflammatory condition present. The question might arise as to what constitutes an inflammatory condition. If we simply mean a process characterized by cell and tissue change then we must acknowledge lupus erythematosus to be an inflammatory disease. I am inclined to the belief that in a great many cases lupus erythematosus is due to a toxemia generated as a result of an illy defined or latent tubercular process, existing in the patient, in some portion of the body distant from the seat of the lupus erythematosus.

DR. W. T. CORLETT, Cleveland—Speaking from a clinical standpoint I have never been able to associate lupus erythematosus with tuberculosis, and lupus erythematosus is a comparatively common disease. I have seen many cases which were looked on as peculiar manifestations of lupus erythematosus by others, but it was not patent to me. Neither can I agree with the last speaker, that lupus erythematosus is a product of the tubercle bacillus, because, as I have said, in my own cases I have not been able to associate lupus erythematosus in any way with tuberculosis.

DR. L. WEISS, New York—In 1890, when Koch's lymph came into use and for the study of which I happened to be on the other side of the ocean—as is the case now with the *x*-rays—we tried to enlarge its use and to apply it to several skin conditions. So it came that tuberculin was used tentatively in many skin diseases, and Dr. Buzzi of Berlin and myself made a few tuberculin tests at Professor Schweninger's clinic, by inoculating several lupus erythematosus cases and two cases of lichen scrofulosorum. One of the latter reacted and of the half dozen lupus erythematosus cases three reacted. In one case a history of remote tuberculosis in the family could be ascertained, but in the other two cases there was none. It seems to me, therefore, that lupus erythematosus must have some connection, at least in some cases, with tuberculosis, and the contention of Dr. Campbell, that toxemia of tuberculosis may in

some unknown way cause a modified tuberculosis and an eruption of lupus erythematosus, is quite tenable after what these injections of tuberculin have taught us.

Dr. L. Duncan Bulkley, New York—In regard to the age of patients with lupus erythematosus, I certainly do not believe that the young average observed is owing to the early death of many of these patients by tuberculosis. I believe that it is rather due to the fact that the disease is prone to develop in early life, and then after some attempts at treatment, if not speedily cured, the patients give up, and do not seek further medical aid. I have certainly seen patients 60 years old with lupus erythematosus, and I have watched patients with the eruption for many years. I have had the subject of tuberculosis under thought since a possible connection was first suggested, and have repeatedly examined patients for evidences of the same, in vain. I recall only one patient who had lupus erythematosus, who died of tuberculosis; and this among many hundreds of cases in public and private practice.

Dr. M. L. Heidingsfeld, Cincinnati—I am by no means favorably impressed with any effort to bring tuberculosis in causal relation with lupus erythematosus. I believe both clinically and histologically the types are separate and distinct forms of dermatoses, easily recognizable and distinguishable from each other. A few cases may have had both affections coincidentally associated, but I believe that the transitional forms, from one to the other, mentioned by Roth and others, have been largely errors in diagnosis, the affection being one or the other, *ab initio*. Personal experience in one or two instances strengthens me in this opinion. I concur with Pick, who states that we are not justified in bringing tuberculosis and lupus erythematosus in causal relation.

Dr. J. Frank Wallis, Philadelphia—I would like to ask the Doctor in regard to those scrofula cases, whether in their history and in others he has found inoculation to prove that they are tubercular. I have had under my care the past year five or six cases, four in one family. There is no history of tuberculosis. Two other cases that came up later had the same affection, but no history of tuberculosis, and I wondered if any inoculation had been made in any of the cases reported. The cases are still under observation.

Dr. H. W. Stelwagon, Philadelphia—I am surprised that the experience of those present is so different from my own, as in the large majority of my cases it has occurred in tuberculous families. I have never seen a case demonstrated as tuberculosis, but I have been thoroughly impressed with the history given me in my cases that tuberculosis has existed in one or more of the remote members of the family, and I think there is a good deal of clinical evidence in medical literature in the same direction.

Dr. Anthony—In answer to Dr. Hartzell's question, if these cases are included, then tuberculosis is present in 70 per cent. of the cases; if excluded, then tuberculosis is present in about 33 per cent. of the cases where every possible evidence of tuberculosis is considered, such as the death of a relative from tuberculosis, scars in the neck from scrofula in childhood, bone disease of childhood, reaction to Koch's lymph, etc. Where these doubtful evidences of tuberculosis are disregarded, the percentage is much less than 33 per cent.

The cases which I would exclude are those like the following one of Boeck's cases: The axillary glands were removed and found to be tubercular; shortly afterward there appeared on each cheek a sharply defined, symmetrical erythema, which was diagnosed as erythema lupinosum, a transitory erythema which is not the same as lupus erythematosus. Six months later the patient had a swelling of the forearm which the attending physician supposed to be erysipelas, but which proved to be a tubercular periostitis. Then she had the eruption of folliclis on the arms and forehead, next erythematous plaques on the face, and lastly, more than a year after the beginning of the disease, two small plaques of lupus erythematosus behind the ear.

These two small plaques are permitted to dominate the entire clinical picture; they give a name to the disease and furnish one more case to swell the statistics in proof of the assertion that lupus erythematosus is tubercular.

To my mind these are cases in which tuberculosis produces, among a great variety of lesions, one or two lesions which at the present state of our knowledge can not be distinguished from lupus erythematosus either clinically or microscopically. There are very few cases on record in which there was present in the same patient lupus vulgaris and lupus erythematosus. Brocy has reported one such case.

THE ETIOLOGY OF ACUTE ARTICULAR RHEUMATISM.*

GEORGE W. WEBSTER, M.D.
Professor of Physical Diagnosis and Clinical Medicine, Northwestern University Medical School.
CHICAGO.

At the outset, while it may seem trite, it may be well to define the sense in which the term etiology is used as well as to indicate what is meant by the term rheumatism. We here employ the term cause in the same sense as we do in typhoid fever, pneumonia, pulmonary tuberculosis, etc., in which we recognize that aside from the infective agent there must be what some have called the soil, susceptibility to infection varying from extreme susceptibility on the one hand to complete immunity on the other; and that the latter may for certain animals and diseases be variable in degree and also either hereditary or acquired.

In order to limit discussion the term rheumatism will be confined to those cases of non-suppurative arthritis occurring especially in children, but which also occur in the adult. This is the view of Poynton and Paine.[1] They say: "All suppurative arthritis must, we think, be excluded. There may be very possibly a suppurative form of rheumatic arthritis; there may, indeed, be rheumatic suppuration as there are pneumococcus suppurations, but as yet all suppurative conditions must be set aside as a basis for investigation."

We may start with the postulate that it is always an infection. If proof of this be demanded it may be found in the work of Fraenkel[2] in 1892, Sahli[3] in the same year, Lanz[4] in 1893, Singer[5] in 1894, Dana[6] in 1894, Lubarsch in 1896, Achalme in 1891[7] and 1897,[8] Triboulet[9] and Coyon in 1898, Wasserman, Poynton and Paine[10] in 1900, Meyer[11] in 1901, Menzer[12] in 1901, Predtechensky[13] in the same year. A study of this literature shows that there are four principal views in regard to the bacteriology of acute articular rheumatism.

THE THEORY OF A MODIFIED PYEMIA.

The view of Gustav Singer, first published in 1898, is that it is not a distinct disease, but due to streptococcal or staphylococcal infection; in other words, a modified pyemia. This view he again defends vigorously in a recent communication,[14] in which he holds that in the face of his evidence the search for a specific organism is futile. He maintains that the diplococcus previously described by Wasserman, Meyer, Poynton and Paine and others is nothing but the *Streptococcus pyogenes*. He further maintains[15] that polyarthritis is only an occasional occurrence in rheumatism and that rheumatism can not be produced in lower animals. He claims that because of the peculiarity of the circulation of the joints they may be affected by a degree of virulence less than that required to produce a pyemia and that this attenuation is brought about by passage through the adenoid tissues of the throat. The objections to Singer's views are briefly as follows:

---

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank A. Jones, George Dock and J. M. Anders.

1. His results have not been confirmed by other observers, especially by Poynton and Paine.

2. He has not demonstrated the organisms in the joints, but only in the heart and lungs.

3. As so well stated by Poynton and Paine,[16] in the five last cases reported by him, the strepto-diplococci were demonstrated in, and isolated from, the tissues, but no experiments were recorded. They say: "This organism Singer calls the *Streptococcus pyogenes* on account of the morphological and cultural characters. Yet the lesions were non-suppurative and our present knowledge of the morphology and cultural characters of several organisms in the coccus group make any assertions on these grounds as to their exact nature a very doubtful proceeding."

4. He does not admit that rheumatism can be experimentally produced in the lower animals.

5. It does not seem reasonable to suppose that micro-organisms which so frequently cause suppuration should be so uniformly attenuated as to always produce such constant and uniform phenomena and always without suppuration.

6. It does not seem quite reasonable to argue that these joints are more vulnerable because of their lessened resistance, and that yet they are as likely as any other structures to be affected by a virulent culture.

7. His hypothesis must carry with it the idea of a constitutional predisposition to suppurative infections.

8. If due to streptococcus infection, the use of the antistreptococcus serum ought to be curative or at least helpful.

ACHALME'S SPECIFIC GERM THEORY.

The second view is that of Achalme,[17] that acute articular rheumatism is the result of infection by a specific anaërobic bacillus which is of large size and possessed of remarkably variable morphologic characteristics. In the papers published in 1891 and 1895 he claimed that the organism is found with constancy, and that rheumatic fever was produced by it in rabbits. Poynton and Paine[18] failed to confirm the results of Achalme, but found a bacillus similar to the one described by him, which they found to be the lactic acid bacillus. Since then they carefully sterilized their media and incubated it over night.

Fullerton[21] expresses the belief that Achalme's work was not well done and that it was most improbable that the organisms which he describes has anything to do with the disease. Rist[19] says "that the organism described by Achalme has been found very often in a number of cases, pathologic or not, where rheumatism was out of the question."

Achalme now reviews[20] his former work and states his belief that his bacillus is to be found in the healthy individual and that it is an ordinary saprophyte whose development in the blood is favorably influenced by the action of heat or cold.

THE THEORY OF VARIED INFECTIONS.

The third view is that acute rheumatic fever is not due to any particular organism, but is a particular reaction to varied infections. In other words, that we may have a uniformity of lesions with a multiplicity of causes. This is too general and includes too much. It makes rheumatism a synonym of arthritis. For example, it is well known that the gonococcus, the pneumococcus, the bacillus of tuberculosis, or the staphylococcus may cause arthritis, and yet we no longer call these cases rheumatic. Gradually there is being formed a rather larger class of cases designated as arthritis, to which the appropriate descriptive adjective is prefixed, as gonorrheal arthritis, pneumococcus arthritis, tuberculous arthritis, etc. If this is followed out to its legitimate conclusion it will be a question of simply calling all inflammatory affections of the joints arthritis and then determining the particular organism causing the inflammation. If it shall be found that all those cases of non-suppurative inflammation of a constant type are always due to a specific germ, then for these the term rheumatism may be reserved, but there is no particular advantage in doing so.

THE DIPLOCOCCUS OF POYNTON AND PAINE.

The fourth view is that of Poynton and Paine. In January, 1899, Poynton and Paine[22] undertook the study of the bacteriology of rheumatism with the intention, if possible, of confirming the results of Achalme. In this they failed and abandoned the attempt. In eight successive cases, however, they obtained a diplococcus which grew in streptococcal chains, which did not thrive on ordinary agar or on serum agar, grew indifferently on blood agar and appeared to grow best in a liquid medium of milk and bouillon, rendered slightly acid with lactic acid. These organisms were isolated in pure culture on three occasions, from the blood of patients during life who were suffering from acute rheumatic pericarditis; also from the pericardial fluid after death, from the valves of the heart and the throat of the patient; fragments of granulation from the valves of the heart of human beings, and also from the joint exudation, heart-blood, urine from the bladder and cerebro-spinal fluid of inoculated rabbits.

These organisms when inoculated into rabbits produce polyarthritis, bursitis and tenosynovitis, multiple non-suppurative valvulitis and pericarditis, plastic pleurisy and pneumonia, a condition of the myocardium analogous to that found in the human heart as a result of rheumatic carditis. There are multiple joint swellings, wasting and pyrexia, thus closely simulating rheumatism in the human being.

When these organisms are passed from animal to animal similar symptoms are produced, but there is a tendency to increase in the severity of the cardiac with lessened severity of the arthritic lesions. The organisms were found, not on the surface, but in the interior of the valves. In one case of chorea the diplococci were found in the perivascular lymph spaces and capillaries of the pia mater and in some parts of the motor areas of the brain.

In September, 1901, they reviewed[23] the bacteriology of the disease and brought the number of cases up to eighteen. They take the ground that rheumatism is not only an infectious disease, but that it is due to a diplococcus infection, and point out emphatically that "the most ardent bacteriologist does not pretend that the presence of a micro-organism explains all the phenomena of rheumatic fever."

The organism described by Poynton and Paine is undoubtedly the same as that previously described by Triboulet[24] in 1898, and Apert and Triboulet in the same year and by Wasserman and Malkoff[25] in 1899. Litten, as the result of the study of two cases and the inoculation of many guinea-pigs, says[26] that he sees no reason why the diplo-streptococcus should not be regarded as the cause of acute articular rheumatism.

Perhaps the views of Pribram[27] should be mentioned. He maintains that in most cases cultures from the joints and blood are sterile and that where micro-organisms are present they are due to secondary infection, predisposed to by the damaged joint.

The fact that micro-organisms are not found in the exudate in the joint is not against the infection theory. It is exceedingly difficult and sometimes impossible to demonstrate the tubercle bacilli in tuberculous effusions. So generally is this recognized that their absence is considered diagnostic of the tuberculous origin of the disease. Indeed, in these cases of rheumatism the germs are found in the articular structures, in the structure of the valves and vegetations, and it is only in those cases in which they come to the surface in large numbers that the name ulcerative or malignant endocarditis occurs and that many minute emboli are formed.

According to Hamburger[28] the bactericidal power of venous is much greater than that of arterial blood. Consequently, we find endocarditis in the left side of the heart because of its arterial blood. It is well known that the venous engorgement of valvular disease, especially mitral disease, affords almost complete immunity against pulmonary tuberculosis. A large percentage of diabetic patients die of tuberculosis because the formation of sugar restricts the formation of carbonic acid.

Brandenburg[29] has shown that alkali occurs in the blood in two forms, that combined with carbon dioxid and that combined with albumin. The latter are very tenacious of their alkali and the bactericidal properties of the blood are augmented by increasing the amount of diffusible alkali in it. Hamberger found that after determining the bactericidal power of the blood, the addition of carbon dioxid releases the alkali from the albumin, increasing the proportion of the alkali, and this augmented alkali tension markedly increases the bactericidal properties of the blood. He suggests that acid intoxications induce variations in the alkali tension. Hegeler, Tsuboi and Stemmetz long ago showed[30] that the bactericidal action of serum which has been heated to 55 C. is restored by adding highly diluted alkali.

CONCLUSIONS.

1. Many organisms produce arthritis.

2. Probably all cases of acute articular rheumatism are due to infection.

3. Probably all organisms known to cause either acute articular rheumatism or other forms of arthritis also give rise to other pathologic conditions as well.

4. It would thus seem to be not merely a local infection or inflammation, but a general infection, the commonest seat of the principal lesion being the joints, but also involving the heart, both endocardium, pericardium and muscle, occasionally the meninges and other structures and caused by a diplococcus circulating freely in the blood. The diplococcus seems to be merely a germ capable of causing widespread inflammation, and the joints are included in its sphere of action. Just as in pneumonia, we may have a general infection with local manifestations or inflammatory reaction in the meninges, the pleura, the endocardium, pericardium, post-nasal space, peritoneum, lymphatics and lungs, the latter being probably the usual site of the localizing inflammation.

5. It is quite possible that there is some hereditary diathetic or constitutional peculiarity, the nature of which is completely unknown to us, which may favor infections in general, and possibly that of rheumatic infection in particular.

6. That there may be varying degrees of susceptibility depending on exhaustion, depressing influences, as cold and the like, seems reasonable. These are the occasions and not causes. They favor but do not cause.

7. That susceptibility varies greatly there can be no doubt. Whether this depends on alkali tension has not yet been demonstrated, but it seems plausible on the ground of variation in the bactericidal action of the blood. This may explain the value of alkalies in the treatment of rheumatic affections.

DISCUSSION.

Dr. Heinrich Stern, New York—The diversity of the methods employed and the contradictory findings of the various investigators clearly demonstrate that in spite of an apparent clinical justification the supposition of a microbic causation of rheumatic fever is in reality based more on speculation than on facts. Achalme's results are directly contradicted by those of Westphal, Wassermann, Malkoff, Meyer, Predtetchensky and others. Sawthenkow, on the other hand, obtained the same results as Achalme, namely, a specific bacillus. Dr. Webster, if I am not mistaken, made liberal use of the articles of Poynton and Paine. In my estimation it is the easiest thing in the world to be a follower of the theory of bacterial origin of disease. It is convenient and for the time being, at least, it is made to serve a certain purpose. The bacterial theory of the causation of rheumatic fever has relegated to oblivion the old lactic acid theory. Who yet believes in the lactic acid foundation of acute articular rheumatism? If we want to determine the cause of acute articular rheumatism I think we must start from a different point altogether. In those affected with the disease we find two pronounced abnormalities in the blood and the urine. This is, firstly, the increased fibrin formation, and secondly, the deficient output of chlorids. This is the basis on which we should work. Where does the fibrin come from; how did it originate? We know there is an intravascular formation and accumulation of fibrin in acute articular rheumatism. This can only be brought about by the presence of fibrinogen and some salts of calcium. The third factor essential to the formation of fibrin does not interest us at the present moment, and I abstain from mentioning the different contentions as to its nature. We can not have thrombosis or intravascular fibrin formation unless the calcium factor works together with prothrombin and the third factor. Looking now for the anatomic substratum of the affection, we will find that the only tissue involved is white fibrous tissue, principally that of joints. The changes found in the inelastic fibrous texture are the same whether they are located in the articulations themselves, in the adjacent structures, or in the heart. White fibrous tissue is found more particularly in those parts habitually used in locomotion. White fibrous tissue is made up of bundles of fibers held together by an agglutinating substance.

Lime or baryta water, or other weak alkalies affect this cementing material. The alkalies may dissolve the cement completely out of the texture. Now it is possible that the calcium salts which bring about intravascular fibrin formation which at this period exists either in larger quantities in the organism or exerts an increased reactivity, also causes the extraction of the agglutinating material from the white fibrous texture. As a natural result of the lesions in the membranes thus produced we will have a disturbance of the osmotic equilibrium, that is, material will pass through the seat of injury which could not penetrate or diffuse through the normal tissue. The deficiency of urinary chlorids may be also explained in this way. The accumulation of ectogenous material in the synovial sacs, the inflammation of the membranes and structures making up the articulations, and all other phenomena of acute articular rheumatism can be explained by the existence of such a lesion in the white fibrous structure.

DR. FRANK BILLINGS, Chicago—Why is it self-limited?

DR. STERN.—That is easily explained. A given case of acute articular rheumatism is dependent either on the degree of the anatomic lesion and the activity of the fibrin-calcium factors or on the calcium material alone. However this may be, the attack will continue as long as the reactivity of the calcium factors continues. The abrupt onset of the affection, its shifting character, etc.—these and all other pertaining characteristics of acute articular rheumatism are better understood on the basis of this physico-chemical substratum than by taking refuge to pathogenic micro-organisms whose influence as regards production of rheumatic fever, with all due deference to the various observers, has not as yet been demonstrated to me.

DR. J. M. ANDERS, Philadelphia—There is perhaps a unity of opinion that we know little about the so-called arthropathies and in cases of acute articular rheumatism we have instances that belong clearly to the intoxications or infections. As you know, we class both under one large head, acute infectious disease or acute infections. The specific micro-organism may be seen; still, I do not see why they should not be multiple as in ulcerative endocarditis or pneumonia. I do not believe that, at the present day, we can definitely say that any special micro-organism is a constant cause of the disease.

One theory regarding this affection has not been mentioned by Dr. Webster, and that is that the symptoms may sometimes be classed with gout, both being due to a prolonged intaking of proteids and carbohydrates in excess. Again, other determining factors may be absorbed from the alimentary canal, resulting from the action of bacteria on proteids. Still, I think this view simply explains the predisposing, rather than the specific cause of the disease. To my mind, acute articular rheumatism is a disease entity; there is no difficulty in recognizing this in its more typical phases. In the typical forms, and in chronic rheumatism, all probably of some specific nature, we are constantly confused with other forms of arthritis and I know of no way to discriminate these clinically. We should attempt, by every therapeutic resource known, to separate acute articular rheumatism from gonorrheal rheumatism; this is usually easy. We should also separate it from acute polyarthritis and gout. In many instances the tophi in the ears will be of great value in discriminating between them. To discriminate between the two diseases clinically is oftentimes not very difficult. Symptoms of purpura occurring in connection with acute articular rheumatism I believe are not common; when it does occur what is the interpretation? It is probably a toxic purpura, yet it may be due to emboli. Quite recently I saw an instance of acute rheumatism, of typical form, in which purpura developed. Here we are confronted with the question, are they *Peliosis rheumatica*, or Schönlein's disease? Polyarthritis and purpura and wheels guide us in making a diagnosis of acute articular rheumatism. *Peliosis rheumatica* is of rheumatic origin, it is stated. I can not ascribe to this view because the cases that I have seen did not show any cardiac complications. Cardiac complications occur so rarely in *Peliosis rheumatica* that it tends to show that it has a different etiology. I see no more reason for speaking of rheumatic diathesis than for speaking of pneumonic diathesis, or of influenza diathesis. I think such a term is obsolete.

DR. WEBSTER, in closing—Dr. Stern says I claim this to be a type of infection and that I have no reason for such a claim. I said in my paper that an organism had been found which we believed to be at least one of the causes of the disease; that this organism had been found in the blood, in the heart, in exudations in joints, and in various other structures and fluids in the body in both the human being and in the lower animals. These organisms taken from the human being have been inoculated in animals and produced identical lesions in them. If carried through a series of animals the arthritic phenomena were again produced in them. If anyone is not convinced by such evidence, I do not know what evidence is called for; I think it is sufficient to convince anybody. With regard to the calcium salts, etc., I have not gone into this part of the subject. The bactericidal powers of the blood are well known, but the Doctor does not demonstrate anything to us; he has been giving us theories; what I have given has been demonstrated.

ETIOLOGY AND PROPHYLAXIS OF THE CARDIAC MANIFESTATIONS OF ARTICULAR RHEUMATISM.*

JOSEPH M. PATTON, M.D.
CHICAGO.

The scope of this paper is limited to the consideration of two phases of rheumatic cardiopathies which, notwithstanding the relative frequent occurrence of these manifestations and their great importance because of their far-reaching effects, have, until a recent period, been almost as imperfectly determined in the one case and ineffectually managed in the other as when Pitcairn, in 1788, noticed the connection between rheumatism and pericarditis, a relation more fully explained by Dundas, Wells and Latham, or when Baillie and Kreisig observed the association of acute rheumatism and endocarditis, the definite connection of which was shown by Bouillaud, who also introduced the term endocarditis.

RHEUMATISM AS A FACTOR IN HEART DISEASE.

Among the extrinsic causes of diseases of the heart rheumatism has long held the most important position. It has gradually absorbed into its etiologic relations the so-called idiopathic inflammations of the pericardium and endocardium, and even certain myocardial conditions of an acute nature. It is even admitted that many of the so-called hereditary diseases of the heart are probably of rheumatic origin, while it is generally conceded that those cardiopathies of early life which obtain with the entire absence of clinical history, or, at most, an indefinite mention of "growing pains," are of rheumatic origin. In several hundred ambulatory cases of acute and chronic disease of the heart observed during the last ten years, fully 30 per cent. failed absolutely to give any history of rheumatic manifestations, though usually some such history could be traced in the parents or other members of the family. In those presenting primary conditions or exacerbations of chronic states the exhibition of rheumatic remedies invariably gave relief. Sansom believes that practically all cases of heart disease in individuals under 35 years of age are rheumatic, and that practically all fetal endocarditis is rheumatic.

THE ETIOLOGY OBSCURE.

The exact etiologic nature of the relation of cardiac disease to rheumatism has long been in discussion.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank A. Jones, George Dock and J. M. Anders.

With the abandonment of the humoral and nervous theories of the nature of rheumatism, and the growth of its recognition as a distinct morbid entity of infectious nature resembling rather closely pyemic conditions and possibly depending on a specific organism, there developed the belief that the cardiac manifestations of acute rheumatism were, as expressed by Dreshfield in regard to endocarditis, not a complication or sequel, but an integral part of the disease. Whether as such the cause lies in the direct local action of a specific organism, or in the action on the tissues of a chemical poison, the result of infective processes seems not entirely settled. The latter theory, based on such observations as those of Buchner that dead bacilli or their protoplasm will determine a chemotaxis capable of causing tissue changes, or those of Sidney Martin, who obtained staphylococci from the blood of a case of infective endocarditis which could be cultivated and produced a proteid substance which, injected into animals, caused pyrexia, diminished coagulability of the blood, and, with an overdose, death with fatty degeneration of the heart, has its adherents, and will have as long as it is recognized as a possible cause for the joint manifestations of acute rheumatism.

The occurrence of toxic lesions of the heart in nephritis has been cited in support of the toxic nature of the cardiac manifestations of rheumatism. The analogy is not close, however, as the cardiac lesions of nephritis are practically always, in the absence of intercurrent infection, of a degenerative nature, while the diffuse myocarditis of rheumatic origin is inflammatory in type, and is usually associated with endocarditis or pericarditis, and with which it sustains etiologic relations. Moreover, myocarditis is much more frequently associated with toxic conditions of the blood not rheumatic than an acute lesion of the covering of the heart or of the lining of its cavities, while the latter are much more frequently associated with rheumatism than are acute myocardial changes. If a chemical agent be the causative factor in the production of the cardiac manifestations of articular rheumatism, then it must be one which has a peculiar affinity for the fibrous tissues of the heart, and different from all the other toxic substances which affect this organ. In a certain proportion of cases there appears a degree of myocarditis which can not be explained by extension of inflammation or by embolic or other direct infective processes, and we must assume with Hanot that toxins are capable of producing acute inflammations of the heart.

THE BACTERIAL RESEARCHES.

The bacterial evidence of direct infection of the heart tissues in rheumatism does not, at present, warrant an assumption other than that the infection is of a polymorphous nature, no specific organism having yet been found with sufficient constancy to cause it to be accepted as the special causative agent for rheumatic carditis. Certain organisms have been by some considered specific for rheumatic lesions of the heart, but at present may be regarded as occupying a position in the bacteriology of these lesions similar to that occupied by the *Bacillus endocarditis capsulatus* of Weichselbaum, or the *Bacillus immobilus et fetidus* of Fränkel and Sanger in relation to the bacteriology of endocarditis in general, and the organisms observed by Klebs, Köster and others in this connection.

Wilson, in 1885, found organisms in the pericardial fluid of a fatal case of endocarditis occurring with rheumatism. Popow (1887) obtained cocci from a blood culture in a case of rheumatism which in rabbits caused "acute articular rheumatism with pericarditis and endocarditis." Achalme (1891) obtained a bacillus by anaërobic culture from the pericardium, blood of the heart, and by direct examination of the pericardial fluid and from sections from the exudate from the mitral valves and sections from the pericardium. Inoculations gave no result. He again (1897) obtained this bacillus from the blood of the heart, the heart valves and the subpericardial tissue. He subsequently found the same bacillus in the blood of a living rheumatic. Triboulet and Coyon (1898) concluded that a diplococcus which they constantly found was the cause of the endocarditis of rheumatism. Intravenous injection of pure cultures caused mitral valvulitis with the diplococcus present in the diseased valves. Westphal and Wassermann (1899) found a recent endocarditis at autopsy of a case of acute rheumatism. Cultures from the blood, brain and mitral valve produced a streptococcus which caused arthritis in animals from whose joints the same micro-organism was obtained. Poynton and Paine (1900) demonstrated what they considered a typical diplococcus of rheumatic fever and endocarditis, which in animals produced polyarthritis, valvulitis, pericarditis and myocardial degeneration.

THREE VARIETIES OF MANIFESTATIONS.

The cardiac manifestations of rheumatism are pericardial, endocardial and myocardial. The importance of their manifestations is attested by the large proportion of cases of rheumatism in which they occur. In this connection they are essentially lesions of early life, and while the well-known laws of Bouillaud in relation to their association with rheumatism are abstractly true, namely, that in acute articular rheumatism of a violent type and general distribution, the coincidence of pericarditis and endocarditis is the rule, and the non-coincidence the exception; that in acute articular rheumatism of a mild type and partial distribution, the non-coincidence is the rule, and the coincidence the exception, yet clinically there is ample evidence of the somewhat frequent association of each of these conditions with the mildest types of rheumatism, and abundant postmortem evidence of their frequent and often unsuspected occurrence, especially of pericarditis, in rheumatism of early life, the statement of Sibson that the means of diagnosing pericarditis are practically infallible, to the contrary notwithstanding. Anders states that both plastic and sero-fibrinous pericarditis may occur in connection with rheumatic dyscrasia without evidence of arthritis.

PERICARDITIS.

According to Baumgarten, pericarditis occurs in about one-third of the cases of acute rheumatism. Anders states that plastic pericarditis occurs in more than one-half the cases of acute articular rheumatism, and Roberts states that the cases of rheumatic pericarditis are more numerous than all the other cases combined; that it is an essential part of the disease and not a mere complication. Sibson states that rheumatic pericarditis is three times less frequent than rheumatic endocarditis and that the latter is generally present also in children. He believes that the production and severity of the pericarditis is related to the increased activity of the heart in rheumatic conditions. Periendocarditis, or carditis, he considers as exclusively rheumatic. Sears reported 100 cases of sero-fibrinous pericarditis, 51 of which were due to acute rheumatism. In 100 fatal cases of heart disease reported by Sturges, pericarditis was present in all but 6. In 150 cases of

rheumatic heart disease reported by Lees, the pericardium was uninvolved in only 9 instances. Twenty per cent. of Sibson's 326 cases of acute rheumatism were complicated by pericarditis. Latham gave 7.5 per cent. and Chambers and Ormerod gave 13 per cent. and 71.7 per cent. respectively.

ENDOCARDITIS.

Acute rheumatism is generally conceded to be the most frequent cause of endocarditis, the observations of Bouillaud as to the frequency of this association being generally admitted. According to Dreshfield endocarditis is not a complication or sequel, but is an integral part of the rheumatic affection, a localization of the rheumatic poison in the tissues of the valves, the mean percentage obtained from various sources being from 20 to 23 per cent.

Of Sibson's 325 cases 107 had endocarditis alone, and 54 endopericarditis. The latter is particularly frequent in children, and Sturges says that "the rheumatic heart inflammation of children when pericardial is always endocardial as well, and when endocardial is extremely likely, with the recurrence of rheumatism, to involve the pericardium also." The incidence of endocarditis in acute rheumatism is stated by Bamberger as 20 per cent. of the cases; by Wunderlich, 9 per cent.; by the Bellevue Hospital report, 33 per cent.; by Anders, 40 per cent.; by West, 61.3 per cent. In children it is variously estimated at from 50 to 80 per cent. The endocarditis most often occurs during the primary attack of rheumatism. In 115 fatal cases given by Poynton it so occurred in nearly one-third of the cases. Bouillaud and Trousseau called attention to the fact that the endocarditis may precede the articular manifestations.

MYOCARDITIS.

The occurrence of acute myocarditis in connection with rheumatism is generally admitted. Lees believes that acute dilatation of the heart occurs from myocarditis in rheumatism, but is less severe than in diphtheria and influenza, probably because of less deleterious effects of toxins on the myocardium. Douglass Powell states that acute myocarditis may be secondary to rheumatism. Leyden regards the myocardial lesion of acute rheumatism as an acute myocarditis.

The general tendency at present to attribute marked dilatation of the left ventricle occurring during the course of an acute rheumatic mitral valvulitis to concurrent myocardial changes rather than to the mechanical effect of the valvular lesion, shows the general recognition of acute rheumatic myocarditis. The occurrence of acute myocarditis by the extension of pericardial or endocardial inflammation occurring with acute rheumatism is recognized by all authorities.

The nature of the pathologic changes, and the possibility of their occurring from other causes than extension, or by embolic processes—that is, from toxic causes—involves discussion foreign to this paper, but my own observation, clinically as well as postmortem, has been that in a certain proportion of cases the extent of the myocardial changes, the degree of the resulting dilatation and the rapidity of its development were not at all in proportion to the extent and severity of the pericardial or endocardial involvement. Anders states that it is probable that myocarditis may occur from rheumatism without involving endocardium or pericardium. Poynton describes a case of rheumatism associated with apparently a primary myocarditis. He calls attention to the fact that severe cardiac involvement may be present without signs of valvulitis. His studies of the pathology of the myocardium in fatal cases of rheumatism shows cellular exudation in scattered foci which are not necessarily dependent on pericarditis. Giacomelli, from experiments on animals with various bacteria and subsequent examinations of the myocardium, concludes that there is constantly more or less marked changes in the heart muscle fibers varying from simple atrophy to fatty degeneration and destruction. Rarely the interstitial connective tissue and vessels are involved by diffuse, lymphoid infiltration. There are no definite lesions corresponding to definite, specific poisons. The changes are due to the direct action of bacterial toxins and poisons on the muscle fiber itself.

The frequent occurrence of toxic degenerations of the heart muscle in dyscrasiæ other than rheumatic exhibit the effect on the heart muscle of toxic agents, and it is possible that in rheumatism the heart muscle may be affected by toxic agents which do not directly affect the less vascular tissues of the epicardium or valves. The most extensive degrees, however, of rheumatic myocarditis are connected with those cases of pericarditis and endocarditis of bacterial association, and continuity of tissue would appear to be the chief element in its production. I believe that some degree of myocarditis is a more frequent element in the cardiac manifestations of acute rheumatism than is generally supposed, and that especially in childhood it is a powerful factor in the severe and rapidly fatal cases of cardiac rheumatism.

This imperfect consideration of this part of the subject is yet sufficient to emphasize the importance of the prevention of cardiac complications in articular rheumatism. These preventative measures pertain not only to the incidence of the more acute phases of the cardiac manifestations, but also to their control when established as preventative of the remote effects.

If we regard the cardiac manifestations as a local manifestation, a feature of the symptom complex, an integral part of the rheumatic disease, the importance of early and effectual control of the rheumatic infection is evident. Sansom says that if the microbic theory be true then the toxins are so slowly evolved as to continue to produce marked changes for months or years, or else the toxins first induce a morbid perversion of metabolism whereby an autogenetic morbid product is formed for an indefinite period. While this appears somewhat too theoretical, it serves to impress the importance of rest during and immediately after the acute period of rheumatism as related to the occurrence of cardiac involvement.

PROPHYLAXIS.

With the treatment of acute rheumatism it is not my province to deal further than to emphasize my belief in the importance, as far as avoiding heart complications is concerned, of early control of the condition as shown by mitigation of the joint symptoms and subsidence of fever, and to express my conviction that this is best obtained by the temporary employment of pure salicylic acid in sufficient dosage to produce relief of pain and fever, with sweating and more or less depression, to be followed by sodium salicylate combined with alkaline diuretics.

The prophylaxis of the cardiac complications of articular rheumatism is constantly engaging more direct effort. There are those who believe that we have no control over the frequency of the incidence of these conditions in rheumatism, and statistics are as notoriously inconclusive on this point as on many others, while the outcome of a give series of cases may furnish the basis for

an entirely different conclusion to the physician who treats the patients than it will to a less directly interested party. Caton's series of 500 cases with a cardiac complication rate of less than 20 per cent. appeals more forcibly to him in support of his method of treatment than to most of us, even though we can not duplicate his statistics.

There is a vital feature to which I am afraid too little attention has in the past been given, especially in the milder forms of rheumatism in children, and that is careful observation of the heart during and for some time after these rheumatic manifestations. We are too much given to considering alterations in cardiac rate and rhythm during the course of rheumatism as depending on the general conditions unless there are murmurs or friction sounds about the heart. We should bear in mind that these signs are neither a necessary nor invariable accompaniment of cardiac rheumatism, that cardiac irritability marked by excited action and rhythmic changes, especially remission and intermission, is an early indication of cardiac involvement, and that when physical signs are evident it is not unlikely that the localization is already beyond our control. Cardiac irritability, therefore, should indicate the institution of measures of prevention, and these should be carried out as thoroughly and persistently as if more positive objective signs were present.

VALUE OF REST AND SLEEP.

It is doubtful if the value of rest is generally appreciated, at least as a therapeutic measure it is often neglected. In children it is particularly important. Sir William Jenner is said to have stated that "children do not grow out of heart disease; they grow into it." Hilton emphasized the fact that rest diminished the action of the heart and afforded opportunity for better nutrition. The views of Sibson in regard to increased heart action and the occurrence of pericarditis has already been stated. Powell has pointed out the importance of rest in children for several weeks after the joint symptoms have subsided, as salicylates may control the joint manifestations and yet the heart is not more able to bear exercise than when the joints were painful and inflamed. He thinks that primary rheumatic endocarditis is frequently curable if the patient continues at rest long enough for the valves to recover before strain is thrown on them. The value of rest is insisted on by Potain, Caton, Thompson and Holt. The latter thinks that in inflammatory conditions of the heart in children rest should be measured by months rather than weeks. The difficulty of keeping the patient at rest is admitted, but the necessity of maintaining the recumbent position until changed to a sitting or upright position is not attended by undue acceleration of pulse rate or change in rhythm can not be too strongly insisted on.

The necessity of sleep is admitted by all, especially in regard to young patients, and yet we too frequently allow the restorative value of sleep to wait on the exhaustion of Nature, when a little timely aid would obviate the nervous strain necessarily attending such a process. Of the hypnotic remedies recommended in this connection the bromids are often unsatisfactory, unless it be the bromid of sodium in connection with small doses of codein. Chloral is, as a rule, too depressing for these cases. Paraldehyd may be efficient, but is so disagreeable as to be practically impossible. Trional is unsatisfactional and often effective. Chloralamid has proven the most satisfactory hypnotic for these cases that I have employed, and it appears to be relatively safe.

DIET AND MEDICATION.

Light, ventilation and diet are important. Diet should consist of concentrated and easily assimilated food. Milk is generally recommended and can not be improved on if the patient takes it well. Potain recommends superalimentation. We must be cautious about crowding food for fear of imperfect digestion increasing cardiac effort and distress.

Of the drugs employed in this connection the salicylates and iodids still hold first place. E. Barie recommends the prophylactic use of iodids, with salicylates for analgesic and antithermic purposes. Potain recommends sodium iodid. Relative to those who doubt the beneficial effect of the salicylates, or profess to believe in their increasing the liability of cardiac involvement, it would appear that as we have definite beneficial effects from their administration in rheumatic conditions generally, and an indefinite understanding of the specific etiologic factor of rheumatic cardiac manifestations individually, it is our duty to give them. Weill, in emphasizing the employment of salicylates to prevent endopericarditis in infantile life, remarks that as to the salicylates predisposing to cardiac involvement, the latter occurs frequently in children who have slight rheumatism and who have not taken salicylates. Packard says that cardiac complications are, to say the least, not increased in frequency by salicylates, and that such apparent effect is probably due to the reduction of pain and fever, allowing the patients to move about before the heart has had time to recover itself.

The alkalies are not yet entirely distanced by the salicylates. Ewart believes that the alkaline treatment reduces the frequency of endocarditis, in connection with diet, through lowering the coagulability of the blood—a property shared by iodid of potash, which, therefore, is to be recommended in threatened endocarditis. William Keen thinks there is less risk of heart complications if the urine is kept alkaline. Personally, I prefer the concurrent use of sodium salicylates, sodium iodid and potassium citrate.

EXTERNAL THERAPY.

The value of external applications to the precordial area for the prevention and mitigation of cardiac rheumatism has been much discussed. According to Gibson, the only two measures which have any influence in preventing pericarditis in rheumatism are the systematic employment of cold by an ice bag, or by iced cloths, or by Leiter's tubes, and the continuous application of blisters after the method of Caton of Liverpool. The latter claims his method of treatment will prevent valvulitis or will check it if instituted sufficiently early. He reports 54 cases in which the heart was involved on admission, and of which 34 were discharged with normal hearts. In another series of 31 cases which developed primary valvulitis while under observation, 28 made a good, and in all but 2, to the best of his knowledge, a permanent recovery. The features of this method of treatment are: 1. Absolute rest in bed in order to protect the valves from pressure. The patient is wrapped in flannel from head to foot. A patient with a true valvular bruit is kept motionless in the recumbent position for a long time to slow the heart and prevent blood waves of high tension from injuring swollen or softened valve cusps. 2. Blisters the size of a florin applied singly and successively over the anterior terminations of the first, second, third or fourth dorsal nerve, above but not over the pericardium. The blisters are followed by small poultices. They are intended to stimulate the

trophic nerves of the heart through the sensory filaments of its related skin area and so hasten absorption and repair. 3. Sodium or potassium iodid in from 8 to 10 grain doses thrice daily, and in some cases small doses of mercury, to help absorption of the, at first, imperfectly organized inflammatory products in the cusps and endocardium.

Sansom recommends the bold and prolonged use of the ice bag over the precordial area. Its continuous use is advocated by Robardet, who protects the skin by a layer of flannel. Thompson recommends leeches, sedative applications and the continued administration of aconite.

The most effectual local measure is the continued application of cold to the precordium. Hot applications have an analgesic effect, and are more readily allowed by children, but their effect on the inflammatory condition of the heart is decidedly less than that of cold. Aconite has a distinctly beneficial effect in quieting the heart and slowing its action, Gibson's assertion that it is entirely useless to the contrary notwithstanding. In the excitable conditions of the earlier stages aconite may be combined advantageously with sodium bromid. In certain rheumatic infections of a mixed type the serum treatment may be advisable, but its relation to the conditions under consideration is not sufficiently definite to warrant its present consideration.

STATIC ELECTRICITY IN TREATMENT OF MORPHINISM.*

A. J. PRESSEY, M.D.
CLEVELAND, OHIO.

Electricity, while not old in medicine, can not be considered new. One of the first advocates of static electricity as a medical agent, I believe, was John Wesley. While endeavoring to educate the people to his ideas of a religious life he spent some time writing and teaching how to apply static electricity for the relief of pain and the cure of certain diseased conditions. He must have given the subject considerable thought and study for much of his advice is as good as that of any of the writings we have at the present time. While there is no doubt in my mind that static electricity may be used to advantage in nearly all forms of neurotic troubles, I shall confine myself in this short paper to its use in the treatment of morphinism.

There is no royal road to the cure of drug addictions. There are no specifics, so that every agent that can be found that is of service in some or all of the cases treated is of value and should be utilized as the conditions of the patients require. In nearly every newspaper and magazine, and I am sorry to say that too often in medical journals we find advertised a sure cure for morphin and other drug addictions where the patient will find freedom from further necessity of the use of the drug in from one to ten days. I have investigated some of them during the past ten years and found them all to be cures that do not cure. Nevertheless, most cases of morphinism can be permanently cured. But as in the treatment of other neurotic diseases, we must have time, the coöperation of the patient, employ any and all agents that have been proven to be useful, and then with the tact and skill that comes with reading and experience every patient can be freed from the addiction, and a large majority can be kept more comfortable during their entire treatment than while taking the drug themselves. I have no faith in either the sudden or rapid withdrawal methods. I have known of many patients treated after each of the above methods and I have yet to find the first case that did not relapse within a very short time after treatment. While I do not doubt that some have been cured permanently by each of the methods, it would appear to me that the percentage must be smaller than by the gradual reduction method, or I would have been able to have found at least one person in all these years who had not relapsed.

Static electricity is in no sense a specific or cure for the morphin addiction, although there are many uncomfortable symptoms that arise during the treatment of some cases that can be relieved with the static machine, for which I was formerly obliged to give an increased amount of morphin. A frequent symptom complained of, when the dose of morphin is a little small, is nausea or vomiting or pain at the epigastrium. Nearly always this can be relieved and the patient kept comfortable until the next regular hour for giving morphin, unless there has been too large a reduction made in the dose given. For the relief of the symptom place the patient on the platform which is connected with one of the prime conductors (I do not care which), then with a brush or single point metal electrode connected with the other prime conductor throw a sharp breeze or spray, or if that does not relieve the pain or nausea some small sparks directly over the epigastric region. The treatment should be continued for about ten minutes or until the symptom is relieved, and should the symptoms return repeat the treatment as often as necessary to keep the patient comfortable, which can many times be done and thereby save giving an extra dose of morphin unless, as I have already said, there had been too large a reduction made in the previous dose. Another frequent symptom is a peculiar nervous sensation of the legs described by patients as pulling of the muscles which, if not relieved, will amount to a severe pain and cramps. I have often been able to relieve this symptom with the use of the breeze or spray and prevent giving morphin. Burning of the feet and legs can often be relieved. Headache is of frequent occurrence and can nearly always be relieved with a breeze from the crown of ten or fifteen minutes. When relieved it is liable to return in half an hour or an hour, but a second or perhaps a third application will usually relieve it for that day. Neuralgic pains or what appears to be neuralgic are very common in patients during the withdrawal period, and I have found the static current very efficient in controlling this very unpleasant symptom. No remedy that I have tried have I had so good success with for the purpose of equalizing the circulation as I have with the static current. Many and many a time patients come to me with hands and feet cold and clammy, features pinched and looking sick when with ten or fifteen minutes of a breeze from the head crown and the other electrode applied to the feet all the symptoms would be changed, the entire skin would be warmed and the patient made comfortable. Sleeplessness can in some cases be overcome by a ten minutes' use of electricity just previous to the patient's retiring for the night.

No remedy with which I am acquainted will so readily and universally correct the heart's action as will static electricity under certain conditions. Should a large part of the patient's ordinary dose be taken away at one time electricity would be entirely inadequate to control the heart. But we will presume that the heart is being properly supported with strychnin or some

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Richard Dewey and H. A. Tomlinson.

other heart tonic and we have made a small reduction in the dose, enough so that the patient is a little weak and nervous. Under these conditions the slightest cause, either mental or physical, is sufficient to increase the circulation 30 to 60 beats to the minute and make the patient very uncomfortable. Under these conditions electricity is a sovereign remedy. Should the heart become slow and weak the same remedy appears to act about as well. In fact, there are but few of the nervous phenomena due to the withdrawing of morphin but may be modified with the static machine.

Valuable as electricity is in relieving the above symptoms, I consider its greatest worth is as a general nerve tonic. There are many cases that would not probably require any electric treatment during the entire withdrawal period, while many others will be in much better condition at the end of their treatment if they take electricity twice a day during the whole period of withdrawal. I make it a rule to give ten to twenty minutes of a general electrization to all patients who come to me as nervous wrecks, such as a majority of morphin patients are, and I feel sure from experience that they recuperate faster and are more comfortable, and I believe that it is of great importance that patients be kept just as comfortable as possible while withdrawing the morphin. Certain it is that one is far from being in a favorable condition for recuperation when he can not sleep or rest at night, nor eat or be at ease during the day. Most patients can be kept comfortable during treatment and made to improve in flesh and general health, a condition much to be desired by the physician and very much appreciated by the patient.

While static electricity can be considered only as one of the remedies to be used in the treatment of this troublesome disease, it has been a valuable one in my hands. I am thoroughly convinced, after years of experience in the treatment of narcotic drug addictions, that those patients who receive the least shock from withdrawal of the drug, or, in other words, those who are kept the most comfortable during the period of withdrawal, are the ones whom we are able to more nearly restore their nervous systems to a normal condition, and as we come nearer to doing this we increase the probabilities of a permanent cure.

A large per cent. of patients will leave the institution as soon as the drug is withdrawn, and they find it possible to get along without the use of it. Unless there has been considerable repair of the nervous system previous to the time of leaving the institution there will be a very large per cent. of relapses. All patients should remain in the institution until they are quite well and strong.

The one unpleasant feature of static electricity is that all the machines that I have any knowledge of are inclined to take a vacation during two or three of the hot months. However, with proper care they can be made to give some current that will be more or less efficient.

To recapitulate. Reduce the morphin so gradually that there is no shock or irritation to the nervous system. Static electricity will be of service in helping to keep the patient in such a condition that the above is possible. The nearer one can keep the patient in a condition of comfort and ease the better and more rapidly will the nervous system recuperate. Static electricity will help us keep the patient in that condition.

Keep the patients in the institution under tonic treatment until they are as near perfect health as possible.

Static electricity is a good nerve tonic.

900 Fairmont Street.

DISCUSSION.

DR. RICHARD DEWEY, Wauwatosa, Wis.—I would like to ask Dr. Pressey if he used the machine with the mica plates. It is claimed that this machine holds its power better than the others.

DR. A. T. GUNDRY, Baltimore—I would like to ask the Doctor about what percentage of permanent cures he records.

DR. PRESSEY—I have never used a mica plate machine. Manufacturers of the machines with mica plates claim that their machines work better in hot, damp weather than machines with glass plates, and I would not be surprised if it were true. I think there is scarcely any agent that will condense moisture more rapidly than glass at the same temperature. Of course, it is the moisture that collects on the plates that prevents generating a current.

As to the percentage of cases permanently cured, that is one of the most difficult things to answer. I find it almost impossible to keep track of patients so as to know whether they have relapsed or not. A very large proportion of the sporting class (both men and women) will relapse. However, some of them will remain cured.

A large part of the patients that I have treated have been well educated, intelligent people who have become addicted through some misfortune, and not from a desire to dissipate. This class want to be cured and to remain cured, and a large per cent. of them do remain cured. Just what that per cent. is I do not know. I have treated some cases the second and third time, and some of these cases have now been cured three and four years and are all right. It is my opinion that with proper care and treatment 60 to 80 per cent. of the better classes may be permanently cured.

PERIPHERAL NEURITIS AS A COMPLICATION OF WHOOPING-COUGH.*

AUGUSTUS A. ESHNER, M.D.

Professor of Clinical Medicine in the Philadelphia Polyclinic; Physician to the Philadelphia Hospital; Assistant Physician to the Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases; Physician to the Hospital for Diseases of the Lungs at Chestnut Hill.

PHILADELPHIA.

Our knowledge of neuritis is of but comparatively recent date. In fact, one of the earliest systematic studies of the subject was made by three American physicians, namely, Mitchell, Morehouse and Keen, whose observations on traumatic neuritis during and following the Civil War have become classical. Isolated cases of neuritis due to other causes had been reported previously, but their nature was not clearly understood and many of them were considered examples of anterior poliomyelitis or spinal muscular atrophy. It was not, however, until 1880 that, largely as a result of the labors of Leyden and others, the clinical and anatomic picture of polyneuritis was established. The etiologic diversity was at the same time recognized and the clinical variability later pointed out. Still more recently the conception of the neuron, comprising the ganglion-cell and its peripheral processes as one continuous whole, has helped to explain on the one hand certain relationships between anterior poliomyelitis and motor neuritis, and on the other hand the similarity between the symptoms of sensory neuritis and degenerative disease of the posterior columns of the spinal cord.

CLASSIFICATION OF CAUSES.

Neuritis may result from a great variety of causes, some of extrinsic, others of intrinsic origin, some local, others generalized in operation, and the character and distribution of the disease will vary accordingly. Num-

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Richard Dewey and H. A. Tomlinson.

erous classifications of neuritis from the etiologic standpoint have been attempted, but owing to imperfections in existing knowledge none yet proposed is entirely satisfactory. Thus Remak,[1] in his article on "Neuritis and Polyneuritis," makes the following classification:

A. Neuritis of local origin.
  1. Traumatic.
    a. From external injury.
    b. From subcutaneous injections.
    c. Without external injury.
    d. Traumatic ascending neuritis.
  2. Neuritis by extension.
  3. Professional neuritis.
B. Neuritis and polyneuritis from internal causes.
  1. Spontaneous (infectious and rheumatic) amyotrophic polyneuritis.
  2. The neuritic form of ascending paralysis.
  3. Peripheral neurotabes and acute polyneuritic ataxia.
  4. Neuritis and polyneuritis attending and following infectious diseases.
  5. Dyscrasic neuritis and polyneuritis.
  6. Toxic neuritis and polyneuritis.

The causes of neuritis are and of necessity must be the same as those of inflammation in general, and I would accordingly suggest the following classification as being most nearly in harmony with current conceptions of the mode of action of the factors concerned in excitation of the inflammatory process:

A. Physical—comprising the effects of extremes of temperature, mechanical influences, and the like.
B. Chemical.
  1. Acting from within (metabolic), such as gout, diabetes, uremia and the like.
  2. Acting from without, such as lead, mercury, arsenic, copper, alcohol and the like.
C. Biologic—comprising infectious diseases.

This classification comprehends all of the causes of neuritis, as well as of inflammation in general. The chemical causes, however, may in their ultimate action be considered as a variety of the physical. Further, the biologic causes must be viewed as essentially chemical, being effective largely, if not wholly, through the activity of the toxic products resulting from the reaction that takes place between the causative micro-organisms and the invaded tissues, although the irritation resulting from the presence of the micro-organisms in the capacity of foreign bodies can not be entirely ignored. Finally, the separation of the metabolic from the biologic is somewhat arbitrary, as from a liberal standpoint the latter also are metabolic, the causative agency in each instance being of cellular origin. The classification proposed may therefore be simplified by including all of the etiologic factors in one great group, namely, the physical, which is subdivisible into: 1, causes that are chemical, and, 2, those that are not. The former comprise: *a*, poisons introduced from without, and, *b*, poisons generated within the body. The first of these may be of infinite variety, while the second are subdivisible into, 1, those of metabolic, and, 2, those of infective origin.

THE SYMPTOMS.

Among the more distinctive symptoms of neuritis are pain, tenderness and swelling in the course of the affected nerves, with muscular weakness and wasting and degenerative electric reactions and alterations in the reflexes. Sensibility may be heightened, particularly at first, but generally it is impaired in greater or lesser degree. Associated with derangement of sensibility there may be ataxia or other disorder of coördination. The condition of the reflexes, superficial and deep, depends upon the state of the factors that enter into the formation of the reflex arc, although reinforcement may be brought about as a result of either local or general influences. Secretory, circulatory and trophic changes of varied kind in the distribution of the affected nerves are not rare and contractures and arthropathies may occur as sequels.

CASES ILLUSTRATING THE CONNECTION WITH WHOOPING-COUGH.

Neuritis appears to be a rare complication of whooping-cough, not even being referred to in this connection in most text-books and systematic treatises, and only a small number of cases of the kind being recorded in the literature. The inflammation may involve one nerve or many nerves, and those of special as well as those of common sensibility. Of cases of the latter variety I have succeeded in collecting those that follow:

Surmay[2] reports the case of a girl, 5 years old, who suffered from an attack of typhoid fever followed by weakness in the lower extremities. Great improvement ensued and the gait became almost normal. After an attack of whooping-cough six months later, however, the previous condition of weakness returned in greater degree, with foot-drop, almost complete paralysis of the extensors and abductors of the feet and of the muscles of the toes, and from which recovery failed to take place.

In this case there appears to have been a polyneuritis complicating the attack of typhoid fever and recurring in accentuated form in the sequence of an attack of whooping-cough at a later date.

A. Jurasz[3] reports the case of a boy, 2 years old, in whom symptoms indicative of paralysis of the posterior crico-arytenoid muscles developed during the course of an attack of whooping-cough. Inspiratory dyspnea was present, with loud, long, snoring sounds and epigastric and suprasternal retraction.

It can not with certainty be determined from the context whether this case is really one of neuritis, but by reason of the isolated character of the paralysis it was thought justifiable to include the report among this collection. The motor disability may be looked upon as due to degeneration of the posterior crico-arytenoid muscles or their intramuscular nervous elements or of the recurrent laryngeal nerve.

P. J. Moebius[4] reports the case of a boy, 3 years old, in whom six weeks after the onset of an attack of whooping-cough weakness was observed in the lower extremities, with absence of the knee-jerks, but with preservation of sensibility. Subsequently paralysis appeared in the upper extremities, although improvement took place in the lower. The muscles of the neck and the diaphragm also were involved. The reflexes in the arms and legs were lost, and the abdominal reflexes were enfeebled, while the cremasteric reflex was preserved. The functions of the rectum and bladder were not affected. Improvement took place and was rapid and progressive, although the knee-jerks were rather slow to return. Moebius describes the case as one of ascending paralysis, and he considers the involvement of the bladder and the rectum, as well as the speedy recovery, indicative of neuritis rather than myelitis.

E. Mackey[5] reports the case of a boy, 6 years old, who on recovery from a protracted attack of whooping-cough following measles, complained of pain and weakness in the arms and legs, of tenderness in the course of the sciatic nerve, of foot-drop, inability to stand and to move the toes, of loss of the knee-jerk and of the

plantar reflex and preservation of sensibility and of the cremasteric reflex. The affected muscles were flabby, but not distinctly wasted, and they at first yielded enfeebled and later degenerative electric reactions. The pupils reacted to light, the action of the sphincters remained unimpaired and swallowing was not interfered with. The patient grew worse for a time, but subsequently he improved slowly, although the knee-jerk had not returned when the report was made.

F. A. Craig[10] reports the case of a girl, 3 1-3 years old, in whom in the fourth week of an attack of whooping-cough paralysis of the left side of the face with internal strabismus of the left eye appeared. This failed to improve after recovery from the primary disease, and was thought to be due to venous hemorrhage into the medulla resulting from the increased pressure to which the veins were subjected in consequence of the violent spasmodic cough. It seems not impossible, however, that the symptoms might be due to inflammation of the sixth and seventh cerebral nerves.

Chas. Leroux,[6] in the course of a paper on the forms of paralysis attending whooping-cough, cites a case reported by Andre Moussous before the Bordeaux Society of Medicine on May 12, 1891. The patient was a child, 18 months old, who, during an attack of whooping-cough, had three convulsive seizures attended with fever and followed on the next day by paresis of the lower extremities, extending to the muscles of the trunk and the neck, without wasting or reaction of degeneration. The voice acquired a nasal character and liquids ingested were regurgitated through the nares. The reflexes could not be determined on account of the movements of the child. Sensibility was unimpaired and the functions of the bowels and the bladder were preserved. For a time there was alarming difficulty in breathing, but subsequently improvement set in and progressed to recovery.

Although this case is reported as one of peripheral origin, the development of the motor disability following convulsions, the mode of extension and the absence of wasting, of degenerative electric reaction and of sensory impairment at least raise reasonable doubt as to the seat of the disease and its character.

M. L. Guinon[7] reports the case of a girl, 5 years old, who, during the subsidence of an attack of whooping-cough, complained of pain in the lower extremities, with paresis, loss of knee-jerks, enfeebled plantar reflexes, weakness of the muscles of the trunk, neck and upper extremities, fibrillary tremor of the tongue, incontinence of urine, bilateral internal strabismus. Some of the affected muscles exhibited partial degenerative electrical reaction, others simple reduction in electrical irritability without qualitative change. Deglutition was not deranged. Improvement gradually took place, but scarlet fever and diphtheria occurred as intercurrent affections.

The foregoing represent all of the cases of peripheral neuritis complicating whooping-cough that I have been able to collect in a cursory search through the literature. I have intentionally omitted from consideration instances of optic neuritis and also cases complicated by deafness and probably due to disease of the auditory nerve, and of each of which a few examples have been reported. Other portions of the nervous system also, brain, medulla, spinal cord, may suffer—inflammation, hemorrhage, thrombotic or embolic softening—in connection with diphtheria, but it would appear from the evidence that the complications involving any portion of this system are uncommon, although it is true that convulsions are not altogther rare at some stage of the disease. To the rarity of paralysis as a complication of whooping-cough Valentin[8] has recently called attention. He was able to collect 83 cases due to all causes, and of these 62 were of cerebral origin, while but four were pontine, bulbar or spinal. P. Horveno[9] had previously stated that but few cases of paralysis of peripheral origin in the sequence of whooping-cough had been reported.

DISCUSSION.

Dr. E. G. Carpenter, Columbus, Ohio—I would like to express my gratification at the new classification suggested. There seems to be so much confusion with regard to classifying the different phases in which neuritis expresses itself. This classification shows that the causes of neuritis have a common derivation, and the internal and the external causes, which are largely toxic, lay claim to the majority of the cases of neuritis. The pathology and histology of the disease bears this out, for the findings show especially changes in the anterior cornua cells, such as simple swelling and those indicating atrophy. Changes also occur in the nerve fibers in which they may be seen as segmented. There are changes in the nuclei, not only of the cells, but also of the neurons, and in the membranes of the vascular system. These changes show that the toxic influences have impaired or destroyed the nutrition of the neuron paths. Speaking again of the classification, frequently different titles have been given to these conditions, such as diphtheritic, alcoholic or puerperal neuritis. You might as well speak of typhoid neuritis, or the name suggested by any other infectious disease. I do not know how to explain these cases of neuritis caused by certain vocations, and would like to have a little light on that subject from the reader of the paper if anything has been given to us to show what changes have taken place in neuritis from a vocation.

Dr. Eshner—I am not quite sure that I gather just what Dr. Carpenter means when he refers to the cases of professional origin. If by that term he intends to include the cases of occupation neurosis, I am somewhat at a loss to answer. The occupation neuroses I am inclined to consider a form of local neurasthenia, if we may be permitted to use such a term. As has been stated on several occasions in this meeting, I think we must look on the whole group of so-called neuroses as expressive of nutritive disturbances. This is a view that I have long maintained, and I consider that factor as the underlying cause in the whole group of cases designated functional and which are attended with more or less definite symptomatology, but in which we have as yet been able to discover no lesions, microscopically or macroscopically. With regard to the disturbance in cases of occupation neurosis, I am scarcely willing to consider it in the nature of neuritis. I believe that certain changes take place, probably in the cells of the cerebral cortex, perhaps in the peripheral nerves. The cases in which neuritis occurs as a result of intoxication, as from lead or mercury or arsenic, or the like, in the course of various occupations are readily susceptible.

Receding Gums.—The application of glycerite of tannin to spongy and receding gums will be found effective. Whether this condition be due to ptyalism or debility following acute disease, the topical use of this simple remedy will be satisfactory.—*Med. Standard.*

A NOTE ON THE CHEMICAL DIAGNOSIS OF HYPERNEPHROMAS (SUPRARENAL TUMORS) OF THE KIDNEY.*

ALFRED C. CROFTAN, M.D.
CHICAGO.

In two recent publications[1] I have shown that a watery extract of fresh suprarenal glands possesses the following properties:

1. Injected into the body of a dog or a rabbit it produces glycosuria (see also Blum's, Zuelzer's and Herter's recent publications).

2. It possesses the power of converting starch into dextrose and maltose and this power of the extract is lost on boiling.

3. It causes the blue color produced by iodin in a starch solution to disappear.

I am indebted to Dr. A. O. J. Kelly of Philadelphia, whose work on hypernephromas is well known, for the suggestion that possibly hypernephromas possessed properties similar to those shown to be possessed by the suprarenals themselves. It seemed possible that an investigation of this question might lead to an additional and important means of differentiating hypernephromas from tumors derived from proper renal structures.

Inasmuch as it was thought that conclusive evidence might not be furnished by old preparations of hypernephromas, the matter remained in abeyance until an opportunity to investigate the subject was afforded by the obtaining of a fresh hypernephroma at a necropsy performed by Dr. A. O. J. Kelly at the German Hospital, April 20, 1902 (Necropsy No. 460). The results attained with this specimen suggested the wisdom of extending the scope of the investigation so as to include (a) that portion of the kidney from this case that was not yet invaded by the tumor growth; (b) several old hypernephromas; (c) a squamous epithelioma developing from the mucous membrane of the pelvis and invading the kidney structures, and (d) fresh normal kidney tissue.

Dr. Kelly has kindly furnished the following description of the fresh tumor:

The fresh hypernephroma was obtained at necropsy from a male subject, aged 42 years. The tumor growth occupied the upper two-thirds of the right kidney which measured 15½x10x7 cm., and weighed 600 grams. The tumor was entirely subcapsular, well circumscribed and consisted of spheroid or ovoid nodules that varied somewhat in size, and that were whitish or yellowish-white in color and moderately firm. The growth was evidently fatty and was somewhat soft in certain regions, but marked retrograde metamorphosis was nowhere to be seen. The growth invaded the pelvis of the kidney but had not penetrated the mucous membrane. Microscopically the tumor consisted of a stroma made up of a rather close network of capillary blood vessels and of cells intimately associated with the capillaries and arranged in rows and larger masses within the meshes of the vascular network. In great part the capillaries were collapsed. The single layer of endothelium of which the capillaries were composed was generally intact. The arrangement of the cells within the capillary network recalled the zona fasciculata of the suprarenal, that is, the cells were arranged in rows and double rows, and in some places in larger masses. Except in the larger masses the cells were attached directly to the endothelium or the capillaries, and this was true also of the more external of the cells in the larger masses. The tumor cells varied somewhat in shape; for the most part they were polygonal, but some were distinctly columnar. The cell protoplasm was faintly granular and contained rather large droplets of fat (in preparations after treatment with alcohol and ether the fat droplets were represented by large vacuoles). Generally the cells were well preserved, being epithelial in appearance; they contained a single nucleus that stained well and revealed distinct nucleoli. Droplets of glycogen also were present in considerable numbers. In the center of some of the larger collection of cells more or less necrosis was present.

THE POWER TO PRODUCE GLYCOSURIA.

Twenty grams of the fresh hypernephroma were mashed into a fine pulp with sand and the mass extracted with 100 cc. of distilled water. Of this extract, after filtration through a gauze filter, 50 cc. were injected into the muscles of the lumbar region of a rabbit. The first urine was passed 10 hours after the injection. It reduced Fehling's solution, turned the plane of polarized light to the right, gave a positive fermentation test and formed a typical dextrosazon with phenylhydrazin. The urine contained 2.47 per cent. of dextrose. The second specimen was voided fourteen hours after the injection and contained 1.65 per cent. of dextrose. The third specimen was passed between the twenty-first and twenty-fifth hours after the injection, and contained only a trace of reducing substance, the nature of which could not be determined. The fourth specimen examined after twenty-nine hours contained no sugar and was altogether normal. The animal recovered. No bile pigment was at any time voided nor was the area of injection discolored as in some of the injections with suprarenal extract already reported.

THE DIASTATIC ACTION.

A watery extract of the fresh hypernephroma was prepared as mentioned above, and equal portions were distributed into several test tubes containing equal portions of dilute starch solution. Four of these test tubes were boiled, four were not boiled. To all of the test tubes 2 *pro mille* of sodium fluorid were added in order to prevent the action of bacteria. At the expiration of 24 hours the tubes were examined for sugar. It was found that the tubes that had not been boiled contained appreciable quantities of dextrose, but that those that had been boiled did not reduce Fehling's solution and did not respond to other tests for dextrose. The conditions found correspond in all respects to those described in regard to the action of suprarenal extract on starch solution. A series of tubes was also prepared in the same manner with glycogen instead of with starch, and it was found that here, too, hypernephroma extract formed sugar, but that no sugar was formed if the extract was first boiled.

THE POWER TO DECOLORIZE IODIN-STARCH SOLUTION.

Equal portions of starch solution having been distributed in several test tubes, hypernephroma extract was added to one-half of them, and then one drop of an alcoholic iodin solution was added to each. Those tubes that contained no hypernephroma extract immediately turned blue and remained blue; whereas those tubes that contained hypernephroma extract turned blue for an instant only and became immediately decolorized. In performing this test care must be exercised not to add too much iodin solution, as in the presence of a considerable quantity of the iodin the decolorization proceeds very slowly. If a great excess of the iodin is added no decolorization whatever may occur, as, of course, the power of the small amount of active substance in the hypernephroma is limited—the decolorization being, in my opinion, a purely chemical process, in contradistinc-

1. Concerning a Sugar-forming Ferment in Suprarenal Extract. A Preliminary Report on Suprarenal Glycosuria. American Medicine, Jan. 18, 1902, vol. iii, p. 113. Das diastatische Ferment der Nebennieren. Pflüger's Archiv für die gesammte Physiologie, 1902.

tion to the sugar-forming power that I consider to be of a fermentative character.

So much having been demonstrated, two old hypernephromas, that had been removed at operation by Dr. John B Deaver[2]—one from a woman, aged 49 years, on April 16, 1899, and the other[3] from a man, aged 45 years, on Feb. 25, 1902, were furnished by Dr. Kelly and investigated by me. Since removal both of these tumors had been preserved in formalin. Both gave a typical iodin reaction, but extracts made from them did not produce glycosuria when injected into a rabbit, nor did they possess diastatic powers. Extracts made from that portion of the kidney not yet invaded by the fresh hypernephroma as well as extracts from other fresh kidney tissue and from the squamous epithelioma developed from the mucous membrane of the kidney pelvis were submitted to these tests with a negative response in each case. The squamous epithelioma of the kidney pelvis had been in formalin and alcohol since May, 1899.

THE VALUE OF THESE FACTS.

In view of these results I believe that it is possible by these simple chemical tests to differentiate hypernephromas from other tumors of the kidney. The last named reaction in particular is so easy and rapid of execution, and so characteristic, even pathognomonic, of suprarenal tissue that, should the occasion arise, it might be made use of as a convenient and time-saving means for diagnosticating hypernephromas immediately at the time of operation or at the necropsy table.

Not the least interesting results of these investigations has been the demonstration that the cells of hypernephromas are not only morphologically identical with suprarenal cells, but that they are also functionally identical with them; and it is especially interesting that this functional activity should be preserved in the large mass of cells making up the massive and malignant hypernephromas which, as is well known, result from proliferation of aberrant suprarenal rests that are often microscopic in size.

It is probable that by means of these tests we may also be enabled to determine the exact nature of certain bodies found in the broad ligament in the female and in the spermatic cord, etc., in the male, and known as Marchand's adrenals. During recent years these bodies have been the subject of much controversy, the question at issue being whether they are to be looked upon as aberrant suprarenal rests or as more or less independent bodies. I intend to apply these tests to these bodies as soon as material can be procured, and I believe that should the tests respond positively we shall be justified in declaring these bodies to be aberrant suprarenal rests, whereas should the tests respond negatively we shall be compelled to conclude that they are more or less independent bodies.

It will be interesting to pursue this line of thought and to endeavor to ascertain whether or not other groups of specific tumor cells found in localities remote from the location of the parent growth (metastases) also possess the functional properties of the organ from which they are derived.

DISCUSSION.

DR. H. R. GAYLORD, Buffalo—I am especially interested in this communication of Dr. Croftan, as for nearly two years we have been looking for a hypernephroma to determine if these tumors contain the adrenal principle. The chemical work was done by Dr. G. H. A. Clowes, chemist to our laboratory. The first tumor examined had been hardened in formalin, and the second proved to be an adenocarcinoma, and for these reasons both gave negative results. We have a number of hypernephromata which we shall now submit to the test which has given Dr. Croftan such interesting results. This line of research is of the greatest importance, and we believe with him, that along these lines lies the solution of many difficult problems.

DR. LEO LOEB, Chicago—In certain cases tumors seem to produce the same substances which are normally produced by the cells from which they originated. In this regard Von Eiselsberg's observation, according to which a metastasis of a tumor of the thyroid prevented the results of removal of the thyroid itself, has especially become well known. It is, however, doubtful if tumor cells are always identical in their chemical activity with the normal cells from which they are derived. Certain investigations might be cited against this view. I also might mention that I observed lately in an animal an epithelial tumor of the mammary gland which neither during nor after pregnancy produced any milk.

DR. E. LIBMAN, New York—Four years ago I performed an autopsy on a young woman who died of diabetes, and found an enormous hypernephroma weighing about seven pounds. I was inclined to think there was some connection between this tumor and the diabetic condition. I am more impressed with such an idea since hearing Dr. Croftan's paper.

DR. CROFTAN—The question of this diastatic ferment in the blood is a very interesting one, but this is not the place to discuss the etiology of suprarenal ferments. My theory is that the suprarenal gland has one of two functions: it either secretes a diastatic ferment which, entering the blood in excessive quantities, converts the glycogen into sugar, causing a flooding of the blood with sugar, or it acts as a disintoxicating organ. As there are a great many cells of the sympathetic type in the suprarenals we can understand how in either case stimulation or inhibition might regulate the amount of diastatic ferment in the blood and in this way control the amount of dextrose poured into the blood.

Some of you may not know that to Dr. Porter more than to anyone else is due the credit of the fact that a laboratory can now be fitted out at a small expense, owing to the many improvements he has made in physiological apparatus and his endeavor to cheapen the cost of same.

A STUDY OF SIR JAMES PAGET IN HIS WRITINGS.*

HELEN C. PUTNAM, A.B., M.D.
PROVIDENCE, R. I.

"Examine men's ruling principles, even those of the wise, what kind of things they avoid, and what kind they pursue."
—Antoninus.

By chance I was searching English medical journals for a special item two years ago, at the time they were containing obituaries of Sir James Paget. My attention was held by the ring of personal affection and esteem in practically every mention. Their essence seemed to be: He was a great surgeon and pathologist, an ideal teacher and lecturer, and the best loved of his profession in Great Britain. Any one of these records in the book of fame would satisfy a large majority; and the wish arose to learn more of their combination in a single individual. The question came to mind: How far may the personality of a scientific man be revealed by his writings?—"the subtlest form," Phillips Brooks has said, "in which biography can take its shape."

In this attempt to answer the interrogation concerning one so lately living and known to many others, whatever of presumption there may seem to be will, I trust, be overlooked in view of the fact that my motive is that his good influence may be prolonged by better acquaint-

* Read before the Rhode Island Medical Society, June 5, 1902. Published by courtesy of the Committee on Publications before appearing in the Transactions. (A bibliography of Sir James Paget will appear in the Transactions.)

ance with his good life which I hope to interest you to make. I shall endeavor not to trespass on his Memoirs, lately edited by one of his sons, but to leave them for your own reading.

HIS EARLY PAPERS SHOW ORIGINAL OBSERVATION.

It is always interesting and often instructive to trace success to its beginnings, to estimate how far from them it advanced and along which of the early lines. There is a fine consecutiveness of development in the writings of Sir James Paget that indicates persistency of purpose and well-balanced judgment. When he was 20 years old a little book appeared by himself and his older brother Charles, "The Natural History of Yarmouth." The entomology was written by Charles, the botany and introduction by James. Curtis, in his British Entomology, calls it "an invaluable abstract of local information, and an admirable example, which I hope to see followed in every county." In the *Lancet,* thirty-two years later, is a letter by him in reply to a request for information, telling of an event in his first year in medical college with which every student of science must feel a thrill of gratulation. He saw the same "spiculæ of bone" in the flesh of a subject in the dissecting room that teachers, pupils and scientists had noticed in other subjects. But Mr. Paget, barely 21, "an intelligent first year student," with the habits of a naturalist such as any boy may acquire, looked closely through his lens, saw that the spiculæ were cysts, in each a coiled up worm; and so, in 1835, *Trichina spiralis* came to be known, a scientific discovery, as Dr. Cobbold, an authority on entozoa, says, "one of the happiest to which Englishmen can point." A good introduction to fellow-students and teachers it certainly was in those early days of the microscope.[1]

The first paper I find with his signature is in the *London Medical Gazette* three years afterwards, and during the first decade of professional life papers appear each year. We notice that home journals and foreign quote them or refer to them with approval; justly, for they have characteristics not commonly found even in older writers. He signs himself "M. R. C. S., Demonstrator of Morbid Anatomy and Curator of the Museum at St. Bartholomew's Hospital." He then adds "Surgeon to the Finsbury Dispensary," and later, "Lecturer on Physiology and Warden of the College at St. Bartholomew's," or "Lecturer on General and Morbid Anatomy." In those days of the infancy of pathology, physiology and museums, these offices could hardly have brought much income. He writes almost exclusively on minute anatomy and physiology, and translations or reviews of scientific work. These two items—his positions and his subjects—with the fact that the numerous papers evidence much time spent in original observation in museums and dissecting room, and much more time in reading many French, German and Dutch, Latin, Italian and English authorities, justify the conclusion that private practice was small, and that he was working faithfully to gain an income and for love of his profession.

His first subject is "On some of the diseases of the papillæ of the cutis"; other titles are "On the blood vessels of tendinous tissues," "The influence of madder on the bones of growing animals," "White spots on the surface of the heart, and the frequency of pericarditis," "Obstructions of the branches of the pulmonary artery." His object in each is to contribute something from his own observations of preserved specimens or of fresh anatomic material, or of his experiments in physics, physiology and chemistry. He outlines the ideas of others, correlating his own, and referring in footnotes to original authorities or to catalogued specimens. In the first essay are very noticeable his methods and even vocabulary of botanic study. His naturalist's habits of close observation, careful reasoning and accurate description are demonstrated by the writings of this period to have been, beyond doubt, a very large part of the foundation on which success was built. "Very, very few are the men," Dr. Billings writes, "who can by and for themselves see and describe the things that are before them."

A WRITER ON PROGRESS IN MEDICINE.

During the second half of these ten years he regularly contributed annual reports of progress in anatomy and physiology to the *British and Foreign Medical Review.* With their abundant references to authorities in any of six languages they are marvels of condensation and analysis. They testify to his good judgment in discriminating between authors and selecting from their observations, manifest now after sixty years. They show rare thoroughness and extent of reading, justice and courtesy to authors and readers, straightforwardness of purpose to present fairly and to make his material as useful as possible to others. It was a high compliment to so young a man to be connected with Dr. Forbes on this remarkable quarterly that probably has had no superior among English periodicals and that did much to raise standards of medical literary work.

We also discover him listed among contributors of articles (unsigned) on surgery and anatomy to the *Penny Cyclopædia.* Special mention should be made of his seventy-five (approximately) sketches of early physicians in Long's Biographical Dictionary, some of them indicating that he criticised their works after his own thoughtful reading. Such study of professional careers by this keen young observer must have implanted many ideas of what is most and least worth while in the conduct of a physician's life, and, with his extensive scientific reading, have had a profound influence in molding his own. It must also have had some considerable share in cultivating his later exceptional ability and interest in character study.

We next find him signing himself "Assistant Surgeon," and publishing his "Lectures on Surgical Pathology" given before the College of Physicians, from which we infer that the preceding ten years of unusual industry were beginning to materialize in professional and financial returns. His writings in those years give evidence of capacity for the hardest mental work and of ambition to serve along every line in his power, pathology, histology, anatomy, physiology and literary effort. He had utilized his minor offices to their fullest extent for acquiring a liberal and accurate fund of information, and by publishing so much he indicated his spirit of helpfulness. His essays are characterized by simplicity of style, accuracy, conciseness; a logical sequence of thought that makes reading easy; a faculty of seeing much in common subjects; a fondness for tracing back to principles, of fitting facts to facts, that adds to the interest and usefulness of what he writes and leaves an impression of truth. They show much shrewd sense, and a love of justice in giving credit where it best seemed to belong. One concludes the author to be a hard-working and alert student, a helpful, stimulating teacher, a young scientist of sincerity and independence without egotism.

1. The history of this discovery is interesting from several viewpoints. It can be traced in The Lancet, 1866 (Paget, Wilks, Presidents of Abernethian, Cobbold and others); Lond. Med. Gaz., 1833 (Hilton), 1835 (Wood, Farre, Owen).

As we glance over those Annual Reports and later writings we find such names as Schwann, Vogel, Henle, Kölliker, Nägeli, Virchow, Pasteur; Liebig, Purkinje, Claude Bernard; Broca, Flourens, Marshall Hall; Darwin, Huxley; Helmholz, Faraday; Dalton, Draper and scores of others that recall vividly to mind the fact that James Paget by his reviews, translating and experimenting was helping introduce the very earliest reports of revolutionizing ideas that flooded periodicals after the invention of the compound microscope: the protoplasmic cell replacing John Hunter's "vital fluid"; the contention of *omnis cellula e cellula* and spontaneous generation; bacteriology, preventive inoculation, serum therapy, parasitic diseases; antisepsis and anesthesia; pathology, histology; our modern physiology and organic chemistry; the laws of atoms and molecules, of electricity, of conservation of energy; the theory of evolution; our knowledge of the nervous system, of reflex action and cerebral localization. Many of these one will recognize as having been a battleground for popular prejudice or for professional myopia.

PAGET'S AVOIDANCE OF CONTROVERSY.

But we find no hint of contention, no "personalities" in what he wrote. He showed sound judgment in selecting "facts, probabilities and guesses" from pages teeming with them, proving himself a cautious thinker who led, as teacher and writer, so discreetly as not to need to retrace his steps. His peaceful course was in part due to his large knowledge that enabled him to look on many sides of the subject, to his truthfulness and zeal for progress that guided him along right lines; to a tactful method of presentation, passing by logical steps from one thought to the next, no assertion without correlation, avoiding non-essentials that might antagonize, and a trained insight taking him to the heart of the subject with clear and simple words. His discussion of antisepsis in 1879, read with other addresses and remarks in the same volume, illustrate this, particularly his pithy common sense, "A patient ought to be cured with as little risk to his life as possible"; "It is not enough that he just escape with his life"—the debate being on whether "partial antisepsis" (cleanliness) was not "just as good," its statistics showing up so well.

He was a leader in matters the subject of controversy yet not a controversialist. By request, I imagine, he wrote for two lay journals on the alcohol question and on vivisection. Dr. Oliver Wendell Holmes condenses his own philosophy in not being drawn into these affrays, in the Professor's "hydrostatic paradox of controversy." "You know that if you had a bent tube, one arm of which was the size of a pipestem and the other big enough to hold the ocean, water would stand at the same height in one as in the other. Controversy equalizes fools and wise men in the same way—*and the fools know it.*" Sir James Paget with his love for humanity and understanding of "the falsehood of extremes," says: "Of course, among the opponents of experiments on animals there are several very different groups, and with some of them it is useless to appeal to reason. Some have committed themselves to the agitation, and can not recede without discredit or more material loss, and some are carried on with so strong an impulse of a mind once made up that they can not pause for a revision of their judgment. . . . That which is most to be desired is that persons with fairly balanced minds, with at least an average both of humanity and of capacity for judgment in cases in which deep feeling may be stirred, should study the whole matter, and judge of experiments on animals as they would of other practices in which utility or even pleasure is pleaded as justifying the infliction of pain."[3]

Concerning total abstinence as the only sure remedy for intemperance, "Here, I can only doubt," he says. "I should think that in this, as in other things lawful yet tempting to excess, the discipline of moderation is better than the discipline of abstinence. But it is certain that we have no facts at all by which to estimate . . . .; we have nothing from which we may make even a fair guess, or which would justify a great experiment. . . . But some will say, what is this moderation? How may we define it? Let those who thus ask try to define, to the satisfaction of any ten persons, what, under all circumstances and to all people, is moderation in bread, or the wearing of jewels, in hunting or the language of controversy."[4]

On both topics he wrote with wide outlook and frank courtesy. Later he spoke on "Science versus Classics" in education, also on "Theology and Science," to which we shall return. Natural law in sociology as in physics seems to be that a centripetal "conservatism" and centrifugal "radicalism" are necessary to generate the median line of true progress. He was in neither extreme, however they may have influenced him, but steadily in the line achieving progress. Yet with all his moderation he could on occasion excel in scathing displeasure, as two or three short notes concerning unethical conduct bear witness.

QUALITIES OF HIS CLINICAL PAPERS.

Reports of his clinics at St. Bartholomew's are found after 1847 for twenty-four years, nearly every week in either the *Gazette, Lancet,* or *British Medical Journal.* While not his writings their brief consideration here may be allowable since they are records, sometimes by shorthand or revised by himself, of his extemporaneous speaking and of his operating. They bring him before us with more reality than do his essays as an accomplished diagnostician, skilful, prudent, ingenious operator, and wise and interesting instructor. We see him as deservingly a leader here as he was along corresponding lines in science and as hard a worker. He was prompt to test new methods, resourceful, original, careful in details, humane; his comments showing again his spirit of helpfulness, sympathetic understanding of students, clearness of expression and thought, large information and experience.

So admirably do these frequent reports reflect the actual surgeon and teacher that one could wish the useful and sometimes brilliant clinics of our own distinguished surgeons could have been or could be preserved with regularity and accuracy in our journals. They would be, as those of Sir James Paget now are, valuable portraits for historian and biographer, as well as helpful to readers not privileged to be present; better often than some of our papers and duplicated abstracts.

It may be admitted of reports of cases and clinical papers that, unless one has some special interest, the majority are read, when they are read, rather from a sense of duty and with uncomfortable effort of mental application. The clinical writings of a few are exceptions, and among the few is Sir James Paget. It is a common experience after reading his first sentences to

3. A characteristic reply follows in Fortnightly Review, 1882.

4. In closing a discussion, carried through several evenings, on the pathology of alcoholism, he comments upon the amount of uncertainty in every subject of this kind when discussed by those who have seriously considered it and are competent to form an opinion; contrasting it with the positive statements by those who know comparatively little of the matter.

continue from genuine interest. Perhaps we may specify a few of the qualities to which the attractiveness is due. His introductory words are simple, are clear and present a genuine thought lighting up his subject. Continuing with easy expression, with rarely a superfluous word or statement, each sentence a definite addition to the development of his thought, his presentation is completed and the reader has found no place to skip because irrelevant or wordy, no weariness because obscure or difficult; but the pleasure that always goes with old ideas well put connecting with new ones evidently true and of value. He has succeeded in what was apparently his wish—that his experience should be as genuinely useful to others as his description can make it.

His clinics and clinical papers, his discussions of cancer and pyemia can well be called, in his words, "Some of Time's old mirrors, upon which, if our thoughts be directed aright, they may be reflected in lessons of wisdom which we may contemplate to our own instruction. . . ." The lecture from which I quote testifies to his scientific spirit in the daydawn of science, to his faith in the future of scientific medicines, his broad philosophy; and it contains an historic bit of humor. While looking through eighteenth century records (to which his happy phrase, "Time's old mirrors," refers) for the origin of the Arris and Gale Lectureship, he finds that at one time the members of the Company of Barbers and Chirurgeons were most indifferent to these lectures on anatomy and surgery. At an executive session it was unanimously voted that each of them who at any time "should attend any of the lectures on anatomy to be delivered in the theatre, should be entitled to and receive the sum of 5 s. out of the cash of the Company." Professor Paget calls this "very cheap devotion of themselves, the principal members of the profession, to the personal encouragement of scientific teaching," and states that not until 1803, when the Company of Surgeons became the College of Surgeons by Royal Charter, did they abolish this "bounty of 5 s. for listening to the Professors."

ADDRESSES AND LECTURES.

In 1862, at the first meeting held in London by the British Medical Association, Mr. Paget gave the Address in Surgery, his subject being "The management of patients after surgical operations." For us of 1902 perhaps no more graphic sketch can be drawn of the state of the best surgical thought and practice just when Pasteur's brilliant investigations of ferments were focusing the observations and hypotheses of others in the question: Why may not communicable diseases, puerperal infection, pyemia, have their origin in germs and be preventable? As became a teacher Mr. Paget did not attempt to answer the speculation; but he impresses us with the urgency of its being the next thing for science to clear up. We see how an earnest, honest, acutely observant, keenly intelligent, humane surgeon struggled in the darkness to find light. In simple words he tells of rigors. "What is the meaning of this strange shuddering preceding, as it so often does, some of the most fearful maladies we have to deal with?" After outlining an autopsy, he says: "We must believe something from the seat of operation passed into the blood and utterly spoiled it." He tells of the improvements in surgical methods by which "we are adding constantly to the list of things that may be done to save life. But on all this, which might be so bright, a cloud rests like a dark pall." The simplicity of his words and the intensity of his searching thought become eloquence, and the impressive picture thrills us who see the answer to all he asks just within his grasp. Many years after, in a plea for acquiring early habits of scientific observation, he said: "It would be a very useful book, I think, if some one would write . . . . a history of the oversights . . . . of things which have been under men's feet, plainly before their eyes. . . . ."

A lecture on "Dissection Poisons" is of special interest because his study of a nearly fatal illness of his own. Commenting on his loss of the immunity which he used to have when dissecting daily, he says: "How it comes to pass we can not surely tell, but the fact of an acquired immunity seems certain. I wish some of you would study these immunities more than any one has yet done. They are of infinite interest in physiology . . . and of still more interest in pathology." This was ten years before the incident of Pasteur's forgotten culture-flask of chicken cholera microbe—the beginning of scientific study of immunities.

FORESHADOWINGS OF DISCOVERIES.

In many other of Sir James' essays we find foreshadowings of scientific discoveries. So extensive and accurate was his information that, knowing the existing limits of knowledge, he looked beyond the barriers with wisdom and courage to indicate where these might and should be broken through. And not infrequently he led the way, as in his "Disease of the Mammary Areola," "Osteitis Deformans," and other papers.

Underneath, throughout and over all his teachings is found by his constant example and speech this precept: The future usefulness of the profession lies in scientific progress; this is to be built up by facts from allied sciences that stand the test of clinical experience, and by our own accumulated clinical studies according to scientific methods; but our first business is to cure the patient, and we are and long will be certain of many remedies which we can not explain. Scientific study carried along with practice he never loses an opportunity to urge and to commend all through his professional record, whether in address, essay or biographical sketch. His criticism is constructive; encouraging, instructing, stimulating. He was a utilitarian in the sense that he valued knowledge and endeavor, and even pleasures, in proportion as they better the individual and society. The "utility of science" is a favorite topic.

His addresses on formal occasions, as the opening of annual sessions or new institutions, his presidential addresses before clinical and pathological societies, the British Medical Association or International Congress, commemorative addresses such as the Bradshawe, Morton, Croonian lectures, light up still more the features of his portrait we have discovered; but the temptation to quote must be cut short. One must often admire the plasticity of simple English as he adapts it with so much ease to fine shades and strong expressions of thought. These addresses bear witness above all to his being a philosopher—a lover of wisdom who does not find it in isolated facts, but rather in such a joining of them together as to create a compact force for good. His intellect traveled around and through his subject, fitting in and adjusting the new-found truths. His chief motive in addressing non-professional audiences was to correlate scientific work with popular life as part of the whole progress of humanity. Indeed, he believed that the general study of science would be the most efficient protection against quackery and anti-science.

Many titles excite one's curiosity, as "The Cause of Rhythmic Motion of the Heart," "Rare and New Diseases," "The Chronometry of Life." I would not men-

tion his "Elemental Pathology"—my own happiest of introductions to his writings several years ago—if it were possible to deny myself the pleasure, it is so fully spoken of in his Memoirs. Of this and his Hunterian Oration one must say, read both, for none will deny them place among our classics. The former traces the likenesses and unlikenesses between human and plant pathology. Before one advances far into this wealth of novel scientific ideas so charmingly set forth, one involuntarily exclaims: "What an interesting man this must be!" We are reminded of Washington Irving and his fluent grace; of Thoreau observing nature so minutely, and seeing in familiar details so much more than the material facts; of Dr. Holmes and his sagacious philosophizings; but the author in "Elemental Pathology" stands out pre-eminent as the brilliant scientist.

He questions into the coloring of autumn leaves and why they are symmetrical as, when younger, he speculated on the causes of pathologic symmetries in man. Many more foreshadowings of scientific discoveries are here, e. g., "In these galls and other similar diseases in plants, we have, it seems, hundreds of specific diseases due to as many hundred specific morbid poisons." After outlining the insect diseases of plants with a suggestiveness that pervades the whole address—for which "fascinating as any romance" is none too much to say—he adds: "It would be difficult to find a field for the study of the very principles of pathology larger or richer than this offers to you."[5]

HIS RELATIONS TO STUDENTS AND EDUCATION.

That he was invited to give so many addresses to students, and their content as well, make us believe him popular among his juniors. They have the same tactful courtesy, practical good sense, earnestness for industry, for scientific medicine and for high principles. He believed in honorable competition since it is a stimulus to better work for ourselves and for the community we serve; and humorously introduces this subject in an address before a "rival" Provincial college by the three queries: "Can one's rival be abolished? If he can, ought he to be so? If he can not, in what condition is it best to have him?" He believed in frequent examinations; "they are the best means of learning how to keep knowledge in such a form that it may be always ready for use." They are excellent training "in the art of thinking during anxiety and other mental troubles." He tells how to pass them, and how to cram for them; about recreations to get back "a clearer head, a stronger will," about how to succeed in practice and the rewards: "Competency of living; the society of educated men; blessings from the poor; recompense, with gratitude, from the rich; boundless fields for intellectual exercise; access to the richest stores of knowledge, for the glory of the Creator and the relief of man's estate; daily inducements to the exercise of the highest Christian virtues." But not wealth, ease or high social or political influence. He teaches that professional success is more in proportion to knowledge than to anything else; but inadequate knowledge is not so great a bar to success as are certain personal defects, such as self-distrust, unbusinesslikeness, discourtesies, disparagement of others. When it is said that a man's success is greater than he deserves, study that man. He probably has some good quality that enhances his professional skill—such as close attention to his cases or the rare gift of common sense. "There is nothing incompatible in intellect and good temper. Knowledge and good manners are not mutually exclusive; the same mind may be scientific and businesslike." He is enthusiastic in presenting the usefulness, dignity and honor of the profession.

His emphatic advice to undergraduates is to "first, last and always combine the study of actual practice with that of the principles and foundations of our profession," . . . "from the beginning to the end of your career, and day by day you must study diseases and their treatment in actual practice. There is nothing of which the observation of the careers of students has made me more sure than of this." Excepting university men with high degrees, "as a constant rule, the best students, and they who have proved themselves the best, not only in the schools, but in after life, have been those who, in the beginning of their studies and for the most part before attending lectures, have been pupils in the provincial hospitals or with active and intelligent general practitioners, who have enabled them to see practice every day and helped them to study it. I am aware that this opinion—that the study of actual practice should extend through the whole period of medical education—is not held by some who have carefully thought upon the subject. . . . . Much of our first learning consists in learning to know things by sight and by other senses, before any consideration of whether we understand them; and much of technical language and of mere routine must be learned, which any one may learn, whether he understand them or not; and many things may be learned and remembered which we may afterward come to understand. And besides all this, there is in practical medicine and surgery a great deal of knowledge which can not yet be, in any proper sense, understood; that is, which can not be reduced to principles, or connected with any laws of physiology or other parts of medical science. Yet it is real knowledge, true and very useful; and it can be gained only in the study of actual disease and its remedies; and there is so much of it that in all the time you can spare, through the whole period of your pupilage, you will not be able to learn it all. But learn all you can of it; for it is eminently the kind of knowledge which is useful in practice, and of which, as years pass on more and more will be incorporated in the true science of medicine. . . . . I do not advise you to study practice to the exclusion of these things [science], but to study it with them and with their help." Elsewhere he speaks of the early special education of the senses "which can hardly be begun too soon and which becomes more difficult the longer it is deferred."

HIS VALUATION OF SCIENCE, CHARACTER AND THEOLOGY.

These opinions he held before 1865, and again in 1890 he says: "You hear a good deal said by some that science is the only way to success; by others that practice is the only way to what is right. After watching for a great many years I am disposed to tell all students now—and I think the rule may hold good for others besides those in medicine—both those should be worked together." After urging faithful devotion to science before and after graduation, he says concerning the belief of some that success in both science and practice is not probable: "it is quite as absurd as the talk that scientific men can not be good men of business, or that they can not have a love of art, or that they can not fully entertain the Christian faith."

One of his opening addresses to students at St. Bartholomew's closes: "But above all, be sure that your

5. It is interesting in this connection to note Dr. S. Weir Mitchell's recent offer of a prize of $50 (annually for a short period) for investigations of the causes bringing about the autumnal coloration of plant parts.

knowledge be not polluted by any irreligion . . . for it is only by joining the study of Revealed truth with that of science, that our science can be perfect. For we stand, as it were, in the centre of an area of light and truth, and whichever way we move, except in one, we come too soon to the twilight, and then to the deep darkness, of that on which the light of science has not yet shone. But, in that one direction there is no twilight; there, if we follow in the line of truth, and do not with a mad conceit refuse the proffered help—there is the path of Revelation, and there the light of science is not lost—it merges in the more glorious light of faith."

"Theology and Science," an address given to students preparing for ordination at the Clergy School at Leeds, might well have for its sub-title, "the philosophy of controversy." He was at that time 67 years old, and it may be taken as his mature thought by which he guided his own conduct. He finds it "a law of our nature that, on all doubtful matters, the vast majority of men refuse to wait for knowledge, and arrange themselves in parties, each of which maintains that itself is sole possessor of the truth." He says it is well to remember that this seems to be "a law of our nature" because it may help to show that some antagonisms are not wholly the fault of those engaged or of the subjects which they discuss. Here we find one of the epigrammatic comments so frequent in his writings: "We love to hold by what we think, for what we think has in it more of ourselves than what we know."

He argued that modern specialization is unifying knowledge and will eventually fill up the intervals by which our beliefs now stand apart: "For future knowledge will not be merely heaped up on the surface of that we now possess; it will penetrate the mass and fill its gaps and interspaces, and make many things one which as yet seem multiple and alien"; as its growth has harmonized many truths apparently in discord, so will it again in science and revelation, although perhaps not in just the ways we anticipate.

HIS SKETCHES OF OTHERS SHOW HIS OWN CHARACTER.

His personal relations with others as shown by his writings were courteous and generous. He was also a keen reader of character. His essay, "What Becomes of Medical Students," indicates that his former position as Warden gave him opportunities which he embraced for comparing early tendencies and their results in after life. This unique analysis could well be reprinted and made easily accessible in every medical college reading room. Its statistics and comments are as impressive as a laboratory demonstration. His conclusion is: "There is scarcely any mental capacity of which the results may not, in the long run, be surpassed by those of constant strong willed resolution." Of his masterly appreciation of John Hunter as man and as physician he says: "After having studied Hunter's life and all his defects of temper and of general culture, of social skill and of all the arts of pleasing, nothing has seemed clearer than that the power of a great intellect, with a strong will and a right aim, is, in the competition of life, sufficient and irresistible; and that, among all the intellects and wills that I have studied, not one was stronger than John Hunter's." But that he would advise another way to success he leaves no doubt.

His life sketches of contemporaries are interesting, not only as studies of character, but as showing what he valued in men's lives and wherein he thought lay failures. Of two promising careers cut off in middle age he says: "Such were the Ormerods. I believe it is not only my affection for them that makes me think their lives should be recorded, both for just praise and for lessons that may be read in them. I only wish that my record could teach all that I studied in them, for to have known them . . . . is one of the responsibilities of my life. Chiefly, they were very dutiful. Whatever came to be their duty, whether through choice or circumstance, they did it with all their might. . . . . And they did not go far away or take much thought to find where or what was their duty. It was always at hand, in the common business of their calling, or if beyond this, in the nearest and best work for which they could fairly, or even modestly, think themselves fit. . . . . Turned from the course of life they wished for, they went into that which then seemed best, and did their best in it. With equal patience they endured the weariness and pain of disease; and not only with patience, but with hope. . . . . They had studied human life in all its aspects and had learned nothing concerning it of which they were more sure than that it was benevolently designed to be the way to an eternal happiness. . . . Over all that were associated with them they had the influence accorded to those who are respected for being always just, virtuous and very prudent, though, on just occasion, not afraid to maintain hard truth; over intimate friends they had, besides, the influence of those who are loved for wisdom, purity, tenderness and watchful courtesy."

It was probably by wise design that he published these and certain other character sketches in the Hospital Reports (St. Bartholomew's) where generations of students can read them.

Of one physician he says: "The rare charm of his personal character moved many to work with him and multiplied the power of his own work." He speaks often of the ability to work with others harmoniously as one of the most important qualities for success. Of two he says: "They included in their duty the striving to find everywhere how they might do more good than in the same conditions had ever been done before." Of another: "He was a strong instance of that fault that sometimes goes with honesty; he was so sure that his convictions were the result of hard and well-intentioned study; so sure that he sought the truth, and sought it on the right way, that he was wholly unable to believe that any one, with equal honesty and almost equal industry, could arrive at conclusions different from his own." Another "was a many-sided man and on all sides good." He likes to mention "the personal and social qualities commanding the confidence of the public. He was gentle in voice and manner; cheerful, warmhearted and kindly in his judgment of others; firm in his friendship, and had a tender-hearted love of home." He loses no chance to commend in their lives any study of natural science which they have kept up, as Edward Ormerod's study of wasps, and several times mentions carpentery as having been a recreation. He especially commends simplicity, clearness and accuracy of speaking, teaching or writing, originality, orderliness, painstaking and dexterity.

In one admirable character sketch he approves business and executive ability. "He was prudent and judicious." "He acted discreetly, persuading, not trying to compel." "He could work with everybody, not because he tried to let everybody have his own way, but because he was always patient, calm and courteous." In debate or controversy "he was liberal, forbearing, gentle." "Everywhere he was a peacemaker."

We believe it legitimate inference that one who so persistently noted these several traits in others, and

whose writings for half a century serve as a confirmatory context, must have modeled his own life accordingly. In a most graceful and tactful address as President of the Section of Surgery of the British Medical Association at Norfolk, in his native county, he recalled the several surgeons he had known more than forty years before when an apprentice, with affection and fine discrimination crediting the good qualities of each. Thus honoring their memories he still more, quite unconsciously, honored himself by disclosing the nobility of his philosophy of judging and remembering others. His frequent appreciation of the good in past work, in history and in men past and present, seems one with his reverence for universal good, with his respect for the individuality of others, and his interest in his students. It could have been no small factor in his influence and in his hold on the affections of others.

While wandering through highways and byways, on southern mornings, searching for an old plantation house, the air musical with bobolinks and mellow voices of toilers in the cotton fields, the Cherokee rose and yellow jasmine swaying out from boughs of stately pines, radiant sunshine and grateful shade, when the homestead was still quite distant, I have felt my quest was nearly ended by a consciousness of some subtile fragrance—all pervasive, yet so delicate as not to be described or easily perceived, even on close approach—the fragrance of the old box borders in the garden; a breath far wafted, yet so elusive that consciousness of it is stronger than of the source from whence it comes.

And so, in tracing Sir James Paget's character through the grace and polish, the science, wisdom and philosophy of his essays and addresses, in addition to the qualities we can indicate, is a subtile, all-pervading attractiveness of personality that we can not find words to make clear; and by our failure we understand better than before the feeling with which his son wrote the last words of his brief preface to the Memoirs: "Other friends have contributed accounts of him as they best knew him. But, for all the good help that has been given the book is not worthy of his memory."

There is no life chronicle—at least I know no other—fitter to put in the hands of a medical student for his help in college days; of a physician for his guide to living in the "waiting years," his wise friend in success, and his consultant in the years of ripening and passing on; and all the charm and interest of its autobiography, its events and quotations have been left quite untouched for your own individual fresh enjoyment; to be supplemented as often as may be by his writings themselves.

Feeding the Cow.—Dr. C. L. Case of Ramona, Cal., has been reading articles on infant feeding and expresses surprise that none refer to feeding the cow to secure suitable milk. He writes to *American Medicine:* "This is the plan I follow: A healthy cow is selected with a calf as nearly as possible the age of the baby, older rather than younger, if a choice is necessary. The cow is given dry feed, plenty of hay and bran, and no green feed for the first two months, and above all no bitter weeds. To begin with I order 2 oz. of boiled milk, 2 oz. of boiled water, 1 oz. of limewater, 5 grains of white sugar, and 1 grain of salt every two hours, to be put into an eight-ounce graduated nursing bottle with no tubes. I gradually increase the milk about ½ oz. each month for each feeding. I also increase the sugar and salt in proportion with the milk, but the other ingredients I leave the same in quantity for about nine months, when the child usually passes from under my care and begins to eat with the family. The intervals between feedings are to be increased 15 minutes each month up to six months and night feeding done away with as much as the child will allow."

BLOODLESS OPERATIONS FOR THE REDUCTION OF DEFORMITIES.*

ADOLF LORENZ, M.D.
PROFESSOR IN THE UNIVERSITY OF VIENNA.
VIENNA, AUSTRIA.

INTRODUCTION.

Complying with the request of your president to appear before this distinguished audience, I must begin with the admission that I feel myself to some extent embarrassed. The reasons for this embarrassment are obvious. More than anything else the feeling disturbs me that I may stir up your resentment by the ill-usage of your fine language—that with every word I may commit the offense which the Frenchman so cleverly calls *ecorcher sa langue*—"to flay his mother-tongue."

Another reason for my disquietude lies in the entire and extraordinary situation in which I find myself through the boundless hospitality of Northwestern University—through the conferring of the degree of "Doctor of Laws" by which I may enjoy the distinction of belonging to the university as an honorary member. I can only assure you that I know how to prize highly this honorary degree.

I must here remark that in the Old World also an honorary title has been given me. You know very well what a great part titles and orders play in the Old World. The title which was conferred on me by His Majesty, the Emperor Franz Josef the First of Austria, reads: "Imperial Counselor of the Government."

Now this old and this new title have a certain inner relationship. This relationship consists in the fact that, without doubt, I am the worst counselor of the government and quite as much without doubt the worst doctor of laws anywhere to be found; for I understand fully as little about government as I understand about laws.

From this it seems to me that the distinction of a degree is so much the greater, the less a man is entitled to it by his respective knowledge. And, therefore, I prize the honor which has been conferred on me through the bestowal of this title of a "Doctor of Laws" as one so high that I feel myself entirely unworthy of it.

If, nevertheless, I accept this honor, it is because I look on it not as a personal one, but regard myself only as the agent of courtesy which the Northwestern University desires to bestow on the long-celebrated School of Medicine of Vienna, a member of which it is my greatest pride to be.

This honoring of one school by another is a beautiful expression of the always deeply-rooted feeling that science is one united power which throws a common bond around all nations; that there are, especially for the medical art and science, no separating boundary posts, no dividing ocean, no different nations. The science of medicine joins her adepts around the world in a great brotherhood, whose common highest law is the law of humanity and brotherly love.

In this sense I accept with deepest thanks the distinction that has come to me, and ask your forbearance and goodness if I shall endeavor in the following to bring before you some remarks of a general nature concerning the character and object of bloodless operations.

THE POPULAR IDEA OF SURGERY AS BLOODY.

The terms "surgery" and "bloodless" appear at first sight, according to general comprehension, each to exclude the other; for surgery is known more than anything else as a bloody art. And yet the word surgery means nothing else than handicraft, technical skill or dexterity. What the hand creates need not mean the shedding of blood. The hand can also caress and coax. But the coaxed of the surgical hand have always certainly a dubious character. In order to characterize bloody surgery, one must speak of it as surgery with the knife. The layman can not conceive the surgical hand otherwise than

* An address delivered before Northwestern University, Nov. 28, 1902, at the conferring of the honorary degree of Doctor of Laws on Dr. Lorenz.

armed with the knife. He thinks as the German poet, Uhland, writes, of the hand of the barbarous king whom the minstrel cursed: "Und was sie schreibt ist blut"—and what it writes is blood!"

The surgical therapeutics of the ancients armed the hand of the surgeon with fire and sword, as is seen from the old sentence: "*Quod medicina non sanat, sanat ferrum, quod ferrum non sanat, sanat ignis, quod ignis non sanat, sanat mors*"—"What medicine does not heal, the knife heals; what the knife does not heal, fire heals; what fire does not heal, Death heals." The flaming sword or the glittering surgical knife should, according to the rule of the ancients, be held by the strong hand of a young man. Ancient surgery demanded in fact the following qualities from the surgeon: "*Chirurgus autem sit juvenis, visu alacri manu strenua nec unquam trepidante; sit im misericors,*" etc.—"The surgeon must be young and gifted with a sharp eye and a hand that never trembles; be merciful," etc. One, indeed, need not wonder that the poor sick man in past centuries perceived in this barbarous, sharp-eyed youth, armed with fire and the sword, the typical surgeon of that time—an executioner rather than a savior. To that was added the terrible certainty of feeling without any relief every motion of the knife, every touch of the glowing iron. Then when the terrible torture was past and the brutal work of the surgeon was finished, his responsibility was at an end, for, to speak briefly, the course of the wound was left more or less to favorable or unfavorable chance.

A celebrated French surgeon of the middle ages, Ambrois Paré, used to say, after the completion of his operation, "*Moi, J'ai vous ai opera, Dieu vous guerisse*"—"I have operated on you; may God heal you!" Modern skill has taken from the dismal picture of ancient surgery much of its terror. Although the surgeon of to-day does also work with fire and the sword; although his eye is sharp, his hand is sure and never trembling; yet his heart is filled with mercy and all his transactions are determined by a feeling of responsibility for his acts. With the finishing of the operation, his responsibility is not at an end; perhaps, in truth, it first begins here. The course of the treated wound is no longer dependent on accident, but will be determined by the sure skill of the antiseptic and aseptic. If the cure does not take the course desired, the modern surgeon no more prays, "*Dieu vous guerisse,*" but he asks himself: "Wherein lies the mistake that I have made?"

If the bloody operation under the protection of modern asepticism has, for the most part, lost its dangers, so it has also, through the help of narcotics, been deprived of practically all of its horror, and dreams may flit about for the patients in those critical moments when the hand of the modern surgeon invades vital organs of which the ancient surgeon had not the remotest idea.

THE FEAR OF THE KNIFE.

But notwithstanding all the progress of surgery and the surgeons, it remains a distinguishing characteristic of human nature to fear the surgical knife and the loss of some of the costly fluid which all vital energy kindles and holds. "Blood is a special kind of sap," very rightly says the poet, and so thinks mankind.

The fear of the knife, however, rules not only the lay public; the doctors also, including the surgeons, do not remain exempt from it. I knew a great surgeon whose daily occupation it was to rummage in the bowels of his fellow mortals, and who himself was so shy of the knife that he could not come to the decision to allow an infectious abscess to be opened with the knife, and who preferred to await in pains the spontaneous breaking of the abscess.

Concerning this, different nations are to different degrees shy of the knife. In general, I have received the impression that the Americans, as a whole, are much less afraid of the knife than are the Europeans. I believe that the American would allow himself to be quartered if thereby he could reach his goal. The greatest fear of the knife rules among the Orientals. The Mohammedans, as a rule, flatly decline an operation, and prefer to allow the celebrated prayer, "*Alah il alah Mohammed rasul Alah!*" to be written on a plate by the hand of a priest, after which they wash off the ink and make use of the water as a remedy. The inhabitants of the Balkans, also, in so far as they are not Mahommedans, characterize themselves by a high degree of fear for the knife and by great vulnerability. It is not easy to compel them to agree to an operation.

Indeed, there is a fear among these shy of the knife that is still greater than the fear of the knife itself—it is the fear of the certain death near at hand, if a life-saving or a life-prolonging operation be omitted. In this lamentable situation there disappears among most men the fear of the knife, and we see that under such circumstances the affair changes sides. The patient begs for the knife and the conscientious surgeon sees himself often enough compelled to deny the request of the patient. "Surgery may not be drawn down to the level of the quickening position," one of my teachers used to say. Speaking in general, the surgical knife remains the "*ultima ratio,*" to its own harm, according to the old rule, "*Principiis obsta,*"—"Resist the very beginnings!"

We can calmly say that with the position of surgical skill at the present day and the high moral worth of contemporary surgeons, the fear of the knife by the layman is unfounded, and the educated public has, for the most part, removed this fear to a distance. There is, however, also a well-founded fear of the knife. This fear of the knife, I conceive when the knife is not the only, and, indeed, not the best means to bring about the cure.

ORTHOPEDIC SURGERY.

Such cases in which the knife does not present itself as the best means for healing belong particularly to the province of orthopedic surgery, that branch of general surgery which concerns itself with the treatment of the misformation and crookedness of the human body, especially in the case of children. In orthopedic surgery the endeavor has been made from remotest times to solve the problems of therapeutics in a bloodless way. But these efforts were nearly fruitless, since the means were entirely insufficient.

A celebrated example of the fruitlessness of this endeavor is afforded by the English poet, Lord Byron, on whom a freakish nature bestowed not only poetic genius but also a club-foot. He carried the club-foot to the end of his life. One of his biographers tells us that Lord Byron in his entire life could not get away from two things: his club-foot and the hypocrisy of his people. A still more celebrated example of the incurability of club-foot with the means then at hand as bloodless surgery is offered by Cardinal Richelieu, who took his club-foot with him to his grave. No more than club-foot could other deformities be brought to cure by the means then at hand in bloodless surgery.

THE DISADVANTAGES OF BLOODY ORTHOPEDY.

From this manifest fruitlessness of orthopedy, it was no wonder that surgery awakened to a new life by antisepticism, seized all problems in orthopedy and disposed of all misformations and crookedness in a bloody way. The principle of this therapeutics was bone resection. So and so much of every bone or part of a bone through whose change of place and shape the deformity depended was extirpated until the crookedness became straight. The principle of operating-orthopedy consisted also of this, to fit the skeleton, that is the bones, to the shortened soft parts. Without doubt, the results reached in this way were remarkable. But important objections may be made to these results; through bone-resetting a deformity may indeed be straightway corrected, but the straightened limb remains crippled, notwithstanding, since the formative groundwork, the skeleton, has become crippled. Such a limb remains shortened, much less adapted to its function. A club-foot, for example, which has been treated with bone-reseeting may be battered partly in its form, but it remains, nevertheless, still a crippled foot, since through the operation it has been shortened, since its joints have become in part destroyed, since its mobility has been lost, so that it can no more lift itself up and perambulate in normal manner on the floor. Let this example serve for many others.

A second objection to the bloody operation in orthopedic surgery is based on the accompanying dangers which are not

less by single operations than are the dangers of the most difficult invasions in abdominal surgery.

We know very well how to meet the dangers, but our certainty never can be absolute, for our measures of precaution always remain incomplete, as in everything human. *"Errare humanum est"*—"It is human to err!"

One should never forget that the orthopedic operations are not demanded as life-saving measures. The operations are not an absolute necessity, the deformity would not hurt life and the patients can reach an advanced age even with their infirmities. The life of the patient, therefore, should never be endangered by an orthopedic operation.

THE JUSTIFICATION OF BLOODLESS METHODS.

From the previously-stated reasons, the endeavor, by the introduction of new and successful methods, to make bloodless orthopedy capable of competing with bloody surgery seems to me to be justified. That bloodless procedure can be successful has been proven for hundreds of years by the crippled feet of noble Chinese women as well as the skulls of South American tribes, modeled to desired forms. But the Chinese method of crippling the foot requires years of care and pains.

In order to be capable of competing with bloody surgery, a bloodless method must give at least as quick and as sure results as the bloody method. If the bloodless method unites the swiftness of the result, with absolute lack of danger, it can become superior to the bloody method.

The foundation of success of bloodless orthopedic knowledge won by experience of the extraordinary plasticity of human tissues, especially the tenderness of it in youth. One can, therefore, characterize bloodless orthopedy as plastic bloodless surgery.

THE MECHANICS OF BLOODLESS ORTHOPEDY.

The essence of plastic bloodless surgery is the extremest conservatism; it forms the strongest opposition to surgery by extirpation and resecting; it takes away nothing from the body, it merely gives the individual parts of it another form. This transformation does not take place through mutilation of the skeleton, or through fitting of the skeleton to the soft parts. Bloodless plastic surgery, on the contrary, opens an entirely opposite way, it regards the bone as somewhat invulnerable and fits the shortened soft parts to the unchanged and unshortened length of the bone.

This fitting on of the soft parts occurs by means of the gradual stretching by manual or instrumental force, exactly regulated as desired, in extreme cases through the subcutaneous tearing of the shortened soft parts. Plastic, bloodless surgery, therefore, regards the youthful tissue as plastic clay, which to a certain extent it remodels in new forms.

The creation of new forms can obviously follow only in the natural way of joint-movement. This way is more or less closed by the crookednesses of the human body, since the bones have been deformed and the mechanism of movement has been destroyed, and since the shortened and shriveled soft parts hinder this movement. The chief problem of plastic bloodless surgery is, according to this, to stretch the shortened soft parts in a bloodless manner until they have the normal length, and to lead back the pathologic joints to postures best adapted for their function.

The direct effect of plastic bloodless surgery is limited to the soft parts. The bones have retained their abnormal form, and have simply been brought into changed relations one to the other. The plastic remodeling of pathologic bone forms into normal forms or those approximating to that which is normal is left to Nature. Nature does not do this voluntarily, but must be compelled to do so. The second, and quite as important, task of plastic bloodless surgery is to create this compulsion.

One means only exists by which Nature can be forced to lead back an abnormally-formed bone to a normal or nearly normal form, and this magic means is "the function of the bone as a carrier." The entire problem of plastic bloodless surgery, therefore, is to transform in a bloodless manner crooked limbs into normal postures, that the same (in this normal position) may be subject to function-rendering. Two simple examples may explain what I mean.

CLUB-FOOT AS AN EXAMPLE.

Look at the congenital club-foot. You can easily construct the picture of such a club-foot if you think of a normal foot rolled up to a spiral, so that the sole of the foot is turned in and the back is turned out. The problem therein consists of unrolling this spiral without disturbing the integrity of the skeleton. As I mentioned already, the resecting of bones is a very barbarous and maiming means, which would not be an unrolling, but a dismemberment of the spiral. The unrolling follows very lightly through the so-called modeling redressment, which either with manual, or in the case of older children, with machine power, stretching out all the shortened soft parts until the spiral becomes unrolled and the deformed bones can be brought into a normal position to each other. If a foot unrolled in such a way be held in its normal position and weighted down with the weight of the body, then Nature, through the law of the *functionelle anpassung*, discovered by J. Wolff, takes care of the restoration of the normal forms, and the club-foot remains permanently healed. The patient himself, so to speak, has trod his foot into the normal form.

CONGENITAL HIP DISLOCATION.

Another classical example for the bloodless plastic surgery is the congenital dislocation of the hip-joint. The problem here is the same in fundamental principles as that of the club-foot. The bones of the hip-joints must first be brought into proper opposition, be held in this position and in this position become subject to the function of weighted carrying.

The bloody opening of the joint pointed out the way to solve the problem of setting the dislocated joint in a bloodless manner. Through the preservation of this reposition and by means of the burden of the weight of the body on the head of the thigh placed in the insufficiently-developed socket, the possibility is given for the socket to deepen itself, and to a certain extent to grow about the head, so that finally it gains the power to retain it permanently.

Should it not be possible to fit the head in the normal place, it can, under the influence of function form a substitute socket, near the normal socket place, and while no ideal healing will be reached in such a case, there will, nevertheless, be a remarkable functional improvement.

Particularly in the treatment of the congenital hip dislocation, plastic bloodless surgery has to boast of its greatest and everywhere recognized results. In the case of the bilateral dislocation, this result is for the laity also a convincing one, especially if it sees the profile of such a child before and after the successful treatment. The completely-deformed body, with its ape-like habit and the ugly, protruding posterior and the prominent belly and the very ugly zigzag attitude has been restored as through a wonder to that normal and beautiful form which blooms, according to our German poets, on Olympus.

A BROAD FIELD FOR BLOODLESS METHODS.

In the two examples mentioned above, bloodless plastic surgery has substituted, for two really dangerous and threatening operations, means that are harmless and bode no danger. The same thing is the case with the wry-neck, a deformity which, if it be treated timely, that is, in childhood, in nowise demands any mutilating resecting of the muscles, but, on the other hand, may be surely and quickly healed in an entirely bloodless manner.

A broad field opens itself for plastic bloodless surgery in the treatment of the angular deformity of the joints. Only in the case of complete bony ankylosis bloody separation of the bones is indispensable. At least 95 per cent. of all the angular deformities of joints are not bony but fibrous, and, therefore, subject to the bloodless plastic surgery. Here the question is one of rapid rectification by means of the modeling redressment and the consolidation of the newly-created relations through the weighting-down function. Grave bloody operations may, in this manner, be avoided. Many problems of orthopedic surgery have not yet been solved by means of the plastic bloodless method. For example, the healing of lateral curvature of the spine is still an open question. Certain it is, that this cure can never be reached by means of operations: If it be at all possible to cure lateral curvature it will be effected in a

bloodless manner and by bloodless methods, which are analogous to the customary methods of plastic bloodless surgery. The lateral curvature of the spine will be overcorrected, and in the overcorrected position be subject to the function of weight-bearing. Until the present time, there has been wanting only the technical skill to carry out this plan. I can not here go into the subject, but I also claim that in the local treatment of tubercular joint diseases in children the bloodless conservative method in all cases shows better final results than the bloody method of treatment by resection. It is a principle of my bloodless treatment to restrain the function only so long as it is painful, that is, for so short a time as possible.

At the end of these detailed statements I should add that general surgery works very often with bloodless means. I recall simply the bloodless treatment of strictures and bone fractures and dislocations which has been a prevalent one for generations.

THE TREATMENTS OF FRACTURES.

In modern times, operative surgery has tried, with little success, to usurp the therapeutics of fractures. When the Röntgen rays taught that it is seldom possible to fit exactly the fractures of bones together one on the other, some surgeons proposed to lay bare every fracture, to fit the broken surfaces exactly together, and then to fasten them by means of nailing. Entirely apart from the wanton danger, called down by this procedure, the functional results throughout were not encouraging. The healing was of long duration; the patients succeeded in getting the use of their limbs later than with the old treatment, which, according to general experience, still had in great part quite satisfactory functional results, even if the anatomic results still left something to be wished for.

AMBULANT FRACTURE CASES.

Certainly the old bloodless treatment had great defects; the greatest and grossest of these shortcomings consisted in the exceedingly long exclusion of the broken limb from every function. Fortunately a reaction is under way against this method. I believe that the total omission of fixation of a fracture and simple massage treatment went too far and shot over the goal. The correct means will be to limit the fixation to the absolutely necessary minimum, and to prepare by massage for the taking up again of the functions. My maxim is to fit the bones well to each other, to fix them very exactly, and for the rest, to treat the fractures by the ambulant method, that is, to allow the patient to go about after a few days. Through the irritation of the function, the healing follows much quicker and surer than by absolute rest. I have had the experience that children who, from whatever reason, had broken the thigh or leg bone, could by suitable fixation of the limb walk about without pain as early as three or four days afterward. It is then my principle to restore as soon as possible the function of the broken bones in order to make use of this function of irritation for quick and sure healing. The care of the soft parts is a matter of secondary importance.

CONCLUSION.

The question is at hand whether the bloodless method can have any kind of a future in general surgery. No one knows. Impossible, however, it is not. At all events everyone filled with the spirit of humanity must wish heartily for it.

At the present time hundreds of wise men of all nations are studying the question whether the cancer, this most terrible scourge of mankind, is of parasitic origin or not. If the cancer is of parasitic origin, as one must hope, and as many of the most respected surgeons believe, then it may be possible that a curing antitoxin will be found. Then the prophesy of the great Joseph Lister, spoken as he gave his fellow beings antisepsis, will be appropriate for the second time: "Surgery will be quite different from what it has been heretofore."

If this boon should come to mankind, then, general surgery also will give way to a very little sharp but harmless instrument—the hypodermatic syringe.

May the twentieth century give to the world, burdened with pain and death, this savior of mankind. The nation which gives birth to this genius will become the first nation of the world through this one deed!

Clinical Report.

REMOVAL OF A SHOE BUTTON FROM THE NASAL PASSAGE.

H. M. CHILDRESS, M.D.
PADUCAH, KY.

In October I was called to see Eva, aged 6 years, who apparently had a severe case of postnasal catarrh. The general health was good. The history of the case is as follows: The first appearance of any trouble in the nasal passage was noticed four years ago. The symptoms at first were mild, but after a year they grew worse, and a slight cold caused the right nasal passage to close up and the right side of the face to become swollen and painful. The trouble finally extended to the right ear, and there was more or less suppuration, with very offensive odor, through the external ear. A physician treated her for catarrh for about three years. I learned that the treatment consisted mainly in spraying the nose with carbolized solutions and the application of various ointments.

I found no marked hypertrophied conditions, which led me to believe the passage was obstructed by a foreign body, and my diagnosis was confirmed when I removed from her nose a shoe button, located between the inferior and middle turbinated bodies, which had by some means gotten into the passage and remained there for a period of four years and had escaped detection. The button was of the ordinary rubber-like composition, and when removed was rough with depressions and abrasions. The wire eyelet crumbled on attempting to pick it up; the rubber composition, however, was still firm and retained its original shape and was perfect except as to the rough depressions. The patient recovered.

Germany's Latest Sanatorium, the Beelitz.—The success of the recent Tuberculosis Conference lay in what was seen rather than what was heard, and the great sanatorium at Beelitz was one of the most interesting sights. It has been recently constructed by the sickness insurance system "Landesversicherungsanstalten," for working people. It is about an hour's ride from Berlin, in the midst of pine groves, and is divided by roads into four parts, completely separating the sexes, and with one quarter devoted to tuberculous subjects who are thus isolated from the other inmates. The aim is always the restoration of the ability to earn a livelihood. The institution is at present arranged for 600 beds. There is a central heating and lighting plant, and the steam is forced through underground pipes to the various buildings. Each bedroom contains two to five beds, but the bathing and washing is in separate lavatories with special arrangements for rinsing the mouth. The inmates are trained especially to extreme cleanliness and care of the mouth. There is no luxury, but all is on the principle that the best is the cheapest in the end, and conveys the impression of luxury. The buildings are constructed with a view to the maximum of light and air. The entire institution is an object lesson of the benefits to be derived from the insurance legislation in Germany and the far-sighted policy of the insurance societies which are spanning the country with a network of sanatoria, as a matter of business.

Ross Combats Malaria in Egypt.—The Suez Canal Company asked to have Dr. Ross sent out to suggest measures to combat malaria at Suez. The local physicians had been studying the cause why mosquitoes were so prevalent in that arid country, although there seems to be no stagnant water for them to hatch in. They found that although the surface is dry, yet there is moisture close to the surface in many places, forming concealed marshes, revealed only by occasional tufts of grass. They found the anopheles at these points, and Ross has already instituted measures for their destruction on the lines that have been so successful in Western Africa.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

103 Dearborn Avenue :: :: Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

SATURDAY, JANUARY 10, 1903.

WHEN AND HOW PHYSICIANS DIE.

During 1902 the deaths of 1,400 regular practitioners of the United States were noticed in The Journal. This is probably within 5 per cent. of the total mortality in the profession of the country, as our facilities for obtaining notices of deaths are very complete. The total number of physicians in the United States is probably about 105,000, and the number of regular practitioners about 95,000. Consequently, the death rate for the year was about 14.74 per 1,000, a lower rate than is usually supposed to obtain in the profession. The statistics of life insurance companies claim a mortality rate per thousand among physicians of 7 at the age of 25; 15 at the age of 35; 21 at the age of 45; 34 at the age of 55, and 112 at the age of 65. The statistics of the United States Census of 1900 show figures which closely parallel our findings. While the details at our command are not sufficiently minute to enable us to make exact deductions, as they were usually derived from lay sources, still an analysis of the recorded cases presents a number of points of interest as regards causation, age at death and length of practice.

Of the 1,400 deaths recorded, in 616, or 44.7 per cent., no cause of death was given, or the cause alleged was so manifestly incorrect or incomplete as to be valueless. The principal causes of death were heart disease, 111; pneumonia, 107; paralysis, 63; tuberculosis, 61; accident, 60; nephritis, 47; typhoid fever, 45; apoplexy, 42; malignant disease, 31; appendicitis, 25; septicemia, 25; suicide, 23, and homicide, 13. Of these causes "heart disease" probably includes a number of cases of so-called heart failure; under "paralysis" are probably classed various nervous diseases terminating in that condition, and "apoplexy" may take in several causative conditions.

In 328 instances, or 23.4 per cent., the ages of the decedents were not given. The extreme limits of age were 21 and 96. Between the ages of 21 and 30, 67 deaths occurred; between 31 and 40, 137; between 41 and 50, 159; between 51 and 60, 173; between 61 and 70, 212; between 71 and 80, 220; between 81 and 90, 94, and 6 deaths occurred in individuals above 90.

The age of greatest mortality was 75, with 30 deaths; then followed 70 and 78 with 29 each; 80, with 28; 64, with 27; 63, with 26, and 35 with 25 deaths. The minimum of deaths, one, occurred at the ages of 21, 91, 93, 94 and 96. A graphic curve representing the deaths of the year in numbers by decades would show a rapid rise to 35, a slight rise thence to 65, a very slight increase from 65 to 75, the maximum. Thence there is a rapid drop, the minimum being reached at 95. A similar graphic curve based on the statistics of deaths of physicians in the United States Census, shows distinct parallelism, but the curve of the mean annual death rate of England and Wales for 1881-1890 rises symmetrically, reaching its maximum at 75. The mean average age of deaths among American physicians in 1902 was 58 years, 7 months and 29 days.

The number of years during which the decedents had practiced also varies within wide limits. In the case of 108, or 7.7 per cent., it was impossible to determine the duration of practice. The recorded limits varied between the year of graduation and 70 years, each with two deaths. In the first decade of practice 219 died; in the second, 246; in the third, 229; in the fourth, 235; in the fifth, 199; in the sixth, 143, and in the seventh, 21. The average duration of practice was 28 years, 10 months and 28 days. The greatest number of recorded deaths was 40 in the twentieth year of practice; 32 in the fifth and twenty-fourth years; 31 in the tenth, thirty-fifth and forty-second years; 30 in the fourteenth year and 29 in the sixth, twelfth and thirty-sixth years. A graphic representation of the length of practice would show a rise in the first and second decades; a slight decline in the third decade, and a slight rise in the fourth, followed by a sudden and progressively increasing angle of decline.

So far as these necessarily incomplete statistics go, they show that physicians lead a relatively sanitary life and that they practice what they preach.

THE CELLS IN INFLAMMATORY PROLIFERATIONS OF CONNECTIVE TISSUE.

The nature and fate of the cells in areas of inflammatory proliferation have been the subject of investigation and discussion among pathologic histologists since the very beginning of cellular pathology. To the student this part of the histology of inflammation no doubt is the reason of much perplexity because of the large number of different kinds of cells that he must learn to recognize and trace to their proper source. For a generation or more it has been taught that the polymorphonuclear leucocytes that migrate from the blood vessels in inflammations do not undergo any further development nor take part actively in the formation of new tissue from which they disappear. The mononuclear forms, or lymphocytes, on the other hand, have continued to offer great obstacles to satisfactory and unanimous agreement as to their exact rôle, especially as regards the formation of new tissue, because of the difficulty in distinguishing between these cells and more or less similar cells derived from the connective tissue or fixed cells, and endowed while young with the powers of locomotion. For a long time the general tendency was to deny all other cells than derivatives of connective

tissue cells the power actively to form new tissue; the more conservative would say that such power had not yet been demonstrated in the case of any white blood corpuscles. The gradual development of improvements and refinements in tinctorial methods and histologic technic in general soon led to renewed, more accurate morphologic study of the cells in question, with the result that special forms were recognized, such as the plasma cell, which hitherto had not been sufficiently well described. Observations were soon made that indicated that the question as to the rôle of the various lymphocytic cells in inflammatory foci was by far not so simple as just indicated. The results of an elaborate reinvestigation of these problems by means of the most improved and elaborate technic have been published recently by Maximow[1] from Ziegler's laboratory. Glass chambers and celloidin tubes were introduced into the subcutaneous tissue of various animals, and the immigrating and other cells studied both fresh on the warm stage and also in fixed preparations. He divides the different cells that enter into consideration into three large groups, the polymorphonuclear leucocytes, the fibroblasts and the polyblasts.

The polymorphonuclear leucocytes are shown once more not to form new tissue. The fibroblasts are derivatives of the fixed connective tissue cells; they are generally long and branched and contain clear nuclei with nucleoli; only occasionally do they become rounded and more like polyblasts. In the formation of connective tissue fibrillæ are described as originating in the superficial parts of these cells.

The polyblasts—the most interesting group because most complicated—are the mononuclear cells of various sizes, heretofore described as lymphocytes, mononuclear leucocytes, plasma cells, and, in the case of larger forms, as epithelioid cells. The majority are traced to mononuclear cells in the blood, but a small part seem to come from wandering cells present in the subcutaneous tissue (rabbits) and from cells in the adventitia of blood vessels, cells that in both cases probably belong to the same form as the lymphocytes of the blood.

The polyblasts are called so because they develop into the most varied cell forms. The lymphocytes from the blood are shown to develop or possess ameboid movements and to constitute a large part of the most important phagocytes, the macrophages, which before have been regarded mostly as fibroblasts. The nuclei and centrosomes are often peculiar, while in many the peripheral parts of the cell body may stain intensely with methylene blue (plasma cells). Maximow believes that this condition corresponds to special functional states in the various cells and that they are not characteristic necessarily of any particular form of cell. The polyblasts do not seem able to form connective tissue fibrils, but they may remain permanently in the tissue as an integral part of it; again, others constitute granular and non-granular cells in the vascular adventitia.

Without going into further interesting details of the varied morphology discussed by Maximow, enough has probably been said to show that the lymphocytes and their derivatives—polyblasts—appear to be entitled to more importance in the inflammatory process than so far given them. They are ameboid and phagocytic, forming a large part of the so-called macrophages. While they do not seem to form connective tissue in the sense that they give origin to fibrils, yet they may remain as permanent but distinct parts of the new tissue. In this sense we may speak of them as hematogenous tissue builders. There is, therefore, much that is new in Maximow's conclusions, and if verified in their more essential points they will mark an important advance in our knowledge of the cellular changes in inflammatory proliferations.

1 Ziegler's Beitr., Supplementheft v, 1902.

ABOLISH THE CORONER'S OFFICE.

The New York County Medical Association has prepared a legislative bill for abolishing the coroner's office in the state of New York. The measure is modeled largely after the Massachusetts law, and among other things it provides for medical examiners who shall furnish accurate and complete information concerning suspicious deaths. The police department or prosecuting attorney is given power to carry the legal investigation of suspicious cases before a magistrate.

It is, indeed, most desirable that this relic of ancient English jurisprudence known as the coroner's office be abolished, and the sooner the better. A more cumbersome, irresponsible, and on the whole useless piece of governmental machinery does not exist than the coroner's office of this country, especially as it appears in our larger cities where the demands for the kind of work it is supposed to do are greatest. In many states the office is a constitutional one, which will make the efforts for its abolishment in those states more difficult. In the matter of practical forensic medicine the United States is far behind other civilized countries because of the failure of the coroner's office to develop and adapt itself to the needs of the modern community. The proper carrying out of the important and highly responsible work naturally expected of the office that the present coroner's office stands for demands well-equipped laboratories for pathologic and toxicologic work manned by trained scientists. Medicolegal institutes of this kind exist elsewhere than in this country. Here this work is given into the hands of untrained men to do in the most unfavorable places, without facilities of any sort and with such apparatus as may be carried in a hand-bag. Corresponding to this shameful state of practical forensic medicine in this country, we find that the subject is neglected in most of the medical schools or given but perfunctory attention in order to fulfill the requirement of some states that instruction be given

in medical jurisprudence. Adequately equipped laboratories for teaching those who desire it the special essentials of forensic medicine do not exist here. The vast amount of suitable medicolegal material daily furnished by our large cities—the medical centers—is unused for instruction of students or for any scientific purpose. There exists but little scientific periodic literature in this important branch of medicine in this country. No doubt this neglected state of affairs is in turn responsible for the numerous and wonderful "battles of experts" that so often disgrace our court proceedings. It is no wonder that justice is heard to have miscarried because of imperfect and incompetent investigations by medical men from the coroner's office.

In the efforts to rehabilitate in adequate form this part of the legal machinery it is the duty of the medical profession to see to it that the steps taken are commensurate with the importance of the object it is sought to accomplish. The state should be asked to furnish not merely competent, trained men, but also properly equipped places for them in which they may do their work. In other words, it is time that special institutes, or medicolegal laboratories, be established in our large cities. Provision must be made, too, for improvements in the methods and facilities for teaching forensic medicine; special laboratory courses should be introduced wherever the material is available and the conditions warrant it.

UNSATISFACTORY REFERENCES BY ANTIVIVISECTIONISTS.

One is impressed, on reading Senator Gallinger's reply to Dr. Keen's letter as published in the newspapers, of the necessity of following Virchow's advice and verifying one's references. From internal evidence it would appear that the honorable Senator paid too little attention to the correctness of his citings and that probably he relied on a defective memory or on a very poorly informed informant. It is not very difficult to find cases of abuse of vivisection, but they no more warrant its prohibition or its restriction to the extent desired by the zoophiles than do the intemperate utterances of the antivivisectionists warrant their extermination. We could furnish him with cases of abuse which have been condemned in our columns, but it would be a great misfortune to mankind if its suffering and death were estimated as not worth some animal sacrifices. Even the beasts would suffer if vivisection were restricted, for veterinary medicine depends as much on animal experimentation as does human healing and more.

It is not our purpose, however, to review Senator Gallinger's arguments or statements, but to ask for better information as to some of the names he quotes. We can understand "Saranelli," but unless the types have done him injustice we might suspect Senator Gallinger of having only a very general and imperfect knowledge of a man whose name he thus misspells. But who are Drs. Pyle of Ohio and B. A. Watson of Jersey City? Dr. W. S. Halstead of New York is also unknown to us, though we have heard of Dr. W. S. Halsted of Baltimore, and do not recall just what in his record is referred to. The only Dr. B. A. Watson in Polk's Directory for 1902 hails from a small Missouri city, and the only Drs. Pyle in Ohio from Toledo and Oberlin. Their records as vivisectionists are unknown to us. Professor Slosson of Wyoming is apparently not a physician, and we admit unfamiliarity with his work. These are points in Senator Gallinger's letter that discredit it to a certain extent. We doubt whether Dr. Keen or any one else is as familiar with alleged instances and authorities, as quoted by the Senator, as the latter would seem to suppose.

In this connection it may be well to say that a Mrs. R. P. White, in a communication to the newspapers, called out by the first letter of Professor Keen to Senator Gallinger, quoted Sir Frederick Treves as an opponent to vivisection. We took the trouble to send the clipping to Sir Frederick and received in reply a statement from which we quote:

> My solitary utterance on the subject of vivisection is contained in an address delivered at Birmingham, in October, 1898 (*Lancet,* Nov. 5, 1898). Speaking of the suturing of intestine, I said that I had found that operations on the intestines of dogs were useless as a means of fitting the surgeon for operations on the human bowel.
>
> Those who are familiar with the controversial methods of the antivivisection party will not be surprised that certain of my remarks have been cunningly isolated from the context and have been used in advertisements, pamphlets and speeches to condemn all vivisection experiments as useless. . . . . No one is more keenly aware than I am of the great benefits conferred on suffering humanity by certain researches carried out by means of vivisection.

This is only one of many misrepresentations of the antivivisectionists, and even after their attention has been called to the misrepresentation, they still keep on.

MEDICAL MEMBER OF THE CANAL COMMISSION.

The New York Academy of Medicine recently adopted resolutions[1] suggesting that, as the health of the workmen engaged on the Panama Canal was in the past the most serious problem in its construction, one of the members of the commission, which the President is authorized to appoint to control the affairs of the proposed canal, should be a medical man. It is further suggested that the amplest powers should be given the medical officers in charge of the sanitation of the canal. These resolutions can only meet with the hearty approval of the medical profession and can scarcely fail of the approbation of any one who realizes how much has been accomplished for the health of Cuba as the result of the proper maintenance of sanitation by the

1. THE JOURNAL A. M. A., January 3, p. 41.

fortunate presence of a medical governor general. The death rate of Havana when the United States handed the government of the island over to the Cubans was scarcely more than one-third what it had been during Spanish rule before the war. The city had actually been converted from a known hot-bed of disease, dangerous for all visitors, into a rather salubrious semi-tropical port, even healthier than many of our larger cities on the American mainland.

Yellow fever and malaria are the most serious of the diseases that threaten the workmen at Panama and practically constitute the main reasons why temperate white workmen should find the tropics dangerous to health. Yet the experience in Cuba and elsewhere shows that these are preventable. Capps[2] has called attention to the need of medical supervision for prophylaxis against uncinariasis, which also may otherwise prove the source of not a small mortality. It would seem that the United States government has one of the greatest opportunities ever offered to demonstrate how much modern sanitary regulations can accomplish for health under presumedly unfavorable circumstances. It would indeed be a matter for pardonable national pride if we could accomplish the constructions at Panama without the terrible loss of life hitherto considered inevitable because of the climatic and pathogenic conditions.

On the other hand, it would be a lasting disgrace if a popular government should neglect any possible precaution to save lives in the work. By all means let us have a medical member of the commission, to whom shall be entrusted, with full powers, all the sanitary aspects of this important problem. If the magnificent work of the governor general of Cuba during our occupation is to be any earnest of the ability of medical men to fulfill executive duties of the very highest order in an exemplary manner, then indeed there is not only ample justification, but even obvious advisability to try further experiments in the employment of members of the medical profession in responsible administrative positions, especially where great sanitary problems are involved.

THE WELTMER DECISION.

The abstract of the recent decision of the U. S. Supreme Court that appears on p. 122, and which we noticed editorially November 29, emphasizes the fact that in the case as presented to the court the averments of the complainant as regards the material facts were admitted in the demurrer, and that the court did not have presented to it the evidence of fraud which is so clear to us as physicians and which was the cause of the postmaster's action. That being the case, it may be that the decision is not criticisable by us, though we still think that some of it is liable to a rather unfortunate construction in some regards. It is hoped that nothing in the decision will rule out the proper presentation of the evidence when the case is reheard and a complete showing up of the fraudulent practice which lead to the original refusal of the privileges of the mails.

2. THE JOURNAL A. M. A., January 3, p. 28.

DANGEROUS SELF-DRUGGING.

As an illustration of one of the popular types of self-drugging, we notice an item which has been going the rounds of the papers for some time, ostensibly coming from a physician's communication in a medical journal, which advises the use of equal parts of peppermint water and spirits of chloroform as a remedy for sleeplessness. Of course, advice is often given in medical journals not intended for the public. The consequences of the general use of spirits of chloroform by the public whenever they can not go to sleep would not be altogether satisfactory to contemplate, and though the physician would probably have to be called in, there might be cases where the outcome might be disappointing. Nothing is said about the dose in the newspaper items, therefore the victims, for that is what we may call them, would have a chance to do themselves up in the most approved fashion. Other items of this kind are extant—this is only one of many—but now and then it is worth while to notice them.

Medical News.

CALIFORNIA.

Personal.—Dr. W. Francis B. Wakefield, Oakland, has returned from a trip abroad.——Dr. Robert F. Rooney, Auburn, fell a few days ago, breaking a bone in his ankle.——Dr. Jose de S. Bettencourt, San Francisco, has returned from eight months' study in Vienna.——Dr. Luther S. Rogers, Tehachapi, celebrated his twenty-fifth wedding anniversary Dec. 27, 1902.

Would Bar Out Consumptives.—The special committee on tuberculosis appointed at the last session of the legislature has decided against the proposition for the establishment of a state hospital for the care of tuberculous patients. It also decided to recommend in its report to the legislature, the adoption and rigid enforcement of more stringent laws governing the admission to California of persons afflicted with tuberculosis.

San Francisco Mortality for November.—The statistician of the board of health reports the total number of deaths during November was 579, equal to a death rate of 19.29 per 1,000 per annum, as against 564 for November, 1901, when the rate was 18.79. During the week ended November 29 there were 165 deaths registered, which is greatly in excess of the normal rate for similar periods in past years. The principal causes of death were: Diphtheria, 14; typhoid fever, 14; cancer, 35; tuberculosis, 77; cerebral apoplexy, 21; diseases of brain 17, of heart 69, of respiratory system (including pneumonia) 57, of digestive system 39; Bright's disease, 25; accident, 50; homicide, 3; suicide, 14.

ILLINOIS.

Bequest to Hospital.—By the will of Mrs. Isabella D. Harwood, Champaign, $2,000 is devised to the Julia F. Burnham Hospital in that city.

The Detention Hospital.—The number of patients admitted to the Cook County Detention Hospital during 1902 was 1,503, the same as for 1901. Of these 899 were men and 604 women; 613 were sent to the Cook County Hospital for the Insane; 248 to the Illinois Northern Hospital at Elgin; 242 to the Illinois Eastern Hospital at Kankakee, and 275 were discharged.

State Board of Health Recommendations.—The biennial report of the State Board of Health recommends that the legislature establish a state home for consumptives; that a state board of medical examiners be created, which shall conduct examinations made under the present law by the State Board of Health. Other recommendations are for better laws to enable the board to suppress contagious disease and safeguard the public health.

Cook County's Sick.—In the year 1902, the County Hospital admitted 19,728 patients, or 1,287 less than for 1901.

More than 1,600 major operations were performed. In August 915 patients were under treatment, or nearly 300 more than the average for that month. This was due to the increase in typhoid fever. More than 900 cases of this disease were treated during the year, with 97 deaths. The aggregate of deaths for the year was 1419, or nearly 7.2 per cent.

Chicago.

Hospital Sold for Debt.—St. Anthony's Hospital on Frankfort Street was sold, January 3, as a result of mechanic's lien proceedings.

Left Money for Hospitals.—By the will of Mrs. Rosa Buehler, $1,000 is bequeathed to the German Hospital and $500 to Uhlich's Lutheran Hospital.

Regulation of Hospitals.—Corporation Counsel Walker has given an opinion that the city has the right to regulate the location of hospitals which can be shown to be offensive or unwholesome. He holds, however, that the police power of the city does not permit it to prohibit hospitals generally as a class from any designated locality.

Lemon Juice and Germs.—The health department says:

Further laboratory study of the action of lemon juice on the typhoid germs confirms the results previously announced. The investigation has been extended to its action on the colon bacillus—first cousin of the typhoid and the cause of diarrheal and dysenteric diseases, which carry off many more victims every year than does typhoid fever at its worst. It is found that the juice from different specimens of fruit varies greatly in destructive power, and the proportion stated last week—one teaspoonful to half a glass of water—is none too much. The action of the acid is instantaneous.

Campaign Against Smallpox.—The commissioner of health, in his annual report, thus sums up the year's history regarding smallpox:

During 1902, 334 cases of smallpox were discovered in the city and removed to the isolation hospital, of which number 322 have been discharged recovered, 4 died, and 8 remain under treatment. The campaign against the disease was inaugurated in January and pushed by the active co-operation of the railway managements in 600,000 square miles of infected territory and among 25,000,000 people. At the time this campaign was begun there had been an increase of more than 900 per cent. in the number of smallpox cases in this territory over the number for the corresponding period of 1901, and 73 per cent. of all the cases in the United States were in the ten states surrounding Chicago. By the middle of October the United States Public Health Reports showed a reduction of 48 per cent. in Chicago territory, and an increase of 124 per cent. in the remainder of the country, in which no such campaign of education and instruction was pursued.

Deaths of the Week, Month and Year.—The abnormally high death rate of December, 1902, continued throughout the week ended January 3, and 628 deaths were reported, an annual death-rate of 17.36, an increase of 30 over the previous week and of 129 over the corresponding week of 1902. The bulletin of the health department says:

The causes showing the greatest increase are pneumonia, bronchitis, cancer, consumption, diseases of the heart and of the nervous system and the deaths from violence.

The December, 1902, deaths have materially raised the rank of the month in the relative mortality scale of the past twenty-two years. For the previous twenty-one years December had furnished an average of 7.9 per cent. of the total yearly mortality, and ranked fifth in lowest mortality. The 2,607 reported deaths last December form 9.8 per cent. of the total 26,455 deaths of the year, and the month now ranks eleventh in the scale, being exceeded only by the month of July, which furnishes 10.7 per cent. of the total mortality of the twenty-two years.

The year's deaths numbered 26,455, or 14.53 per 1,000 of population.

MARYLAND.

Smallpox.—Two cases of smallpox were reported near Emmorton, December 29.——The smallpox conditions on the Eastern Shore are reported by Dr. John S. Fulton, secretary of the State Board of Health, to be as follows: A new case was discovered at Berlin, January 3, in a girl 10 years old. Of the 20 smallpox cases at Snow Hill 13 have been discharged from the isolation house and the others are convalescent. There are 3 cases at Stockton.

Baltimore.

Health Department Banquet.—The annual banquet of the health department was held Dec. 30, 1902, the entire force being present under Dr. Bosley. Dr. William Royal Stokes was toastmaster, and speeches were made by Mayor Hayes, Drs. Bosley and Heiskell and others.

Fumigation Wagons.—The health department has added to its equipment two fumigation wagons. The fumigation of rooms and houses has grown to be one of the most important duties of the department. Heretofore the agents have traveled about with their fumigating machines on the street cars.

Smallpox in Baltimore.—For the first time in more than four months, a case of smallpox was discovered in Baltimore December 29. The patient, a tramp, said he had come from Ohio on a freight train. In less than an hour of his arrival he had been sent to quarantine, and by night every place where he had been had been visited by health officials, and all likely to have come in contact with him vaccinated.

Health Department Extension.—Plans are being matured for the erection of a number of buildings for the use of the health department on land adjoining Bayview Asylum. Among these will be an infectious diseases hospital and a hospital for consumptives. The latter is to be built entirely of iron and glass on the plan of a conservatory. The property to be utilized contains 150 acres. In connection with the infectious diseases institution the cottage plan will be used, each cottage being devoted to the treatment of a separate disease.

Mortality of the Year.—The report of Health Commissioner Bosley shows 10,253 deaths during 1902, as compared with 10,700 for 1900 and 10,479 for 1901. The annual death rate per 1,000 was 18.70, being for the whites alone 16.53, and for the colored 30.76. The death rate was one per cent. less than that of the two previous years. There were 3,327 deaths under 5 years, or 32.45 per cent. of the entire number. Among death causes pulmonary tuberculosis leads with 1,159; pneumonia has 1,010; heart diseases, 716; diarrhea and enteritis (under 5, 695; over 5, 82); Bright's disease, 659; cancer, 384; typhoid fever, 220; diphtheria, 99; whooping cough, 95; measles, 41; scarlet fever, 37, and smallpox, 7.

Insane Hospital Report.—The one hundred and fifth annual report of the Maryland Hospital for the Insane No. 1, at Spring Grove, shows a net cost of maintaining the institution during the past year of $104,800, the expense per capita being $190.45. At the beginning of the year, Nov. 1, 1901, there were 530 patients, 286 males and 244 females, including 22 private patients. During the year 58 males and 55 females were admitted. The whole number under treatment was 643, 344 males and 299 females. During the year 44 were discharged, of whom 15 recovered, 12 were improved, and 17 unimproved. There were 47 deaths. Of causes, heredity was the potent factor in 25 per cent. of all cases, intemperance and old age following in the order named in males; while the most common exciting causes in females were "change of life," ill health and domestic trouble. Dr. Percy Wade, superintendent, recommends the erection of a special building for the criminal insane so as to prevent escapes.

MICHIGAN.

College to Move.—The officers of the Grand Rapids Medical College have decided to move the institution to a more central location.

Sanitarium Destroyed.—Fire on Dec. 13, 1902, destroyed the Reed City Sanitarium. The inmates were all removed in safety. The loss is about $45,000.

Left Estate to Hospital.—By the will of Dr. George L. Elliott, one of the pioneer dentists of Detroit, his entire estate, valued at $15,000, is bequeathed to the Children's Free Hospital.

"Mail Curers" Convicted.—Drs. James M. Peebles, Walter T. Bobo and Charles W. Green of the People's Institute of Health, Battle Creek, were convicted by a jury in the United States District Court, Dec. 22, 1902, of violating the postal laws. A thirty-day stay of proceedings was granted. It was charged that advertisements of their mental "cure" by mail for all sorts of ills constituted an attempt to obtain money by fraud. During the trial Dr. Bobo testified that he believed Dr. Peebles had a healing power like that of Jesus, only that the doctor's power was smaller. Dr. Bobo admitted that if a patient at a distance managed to procure Dr. Peebles' signed instructions and followed them faithfully the cure would not be effective if the patient had not paid the fee of $1.

MINNESOTA.

Smallpox at Hopkins.—County Physician Dr. Jonas M. Kistler visited Hopkins, Dec. 20, 1902, found 9 cases of small pox and quarantined two houses.

New Hospital at Brainerd.—The Order of St. Benedict has completed its $30,000 hospital at Brainerd, and the patients have been moved into it. The hospital is called St. Joseph's, and will be dedicated March 19.

Leprosy in Minnesota.—Dr. Henry M. Bracken, secretary of the State Board of Health, advocates a national home for

lepers. He says that 76 lepers have made their homes in Minnesota, of whom only 16 now live, each being isolated and cared for as well as may be under conditions of isolation.

Personal.—Dr. Willard C. Foster, Minneapolis, as the result of a competitive examination, has been appointed city physician of Manila.——Dr. Charles H. Norred, Minneapolis, has resumed active practice.——Dr. Reynaldo J. Fitzgerald, Minneapolis, who has been in bad health since his return from the Philippine Islands, is reported to have been seriously ill, but his ultimate recovery is confidently expected.

MISSOURI.

To Obviate Substitution.—The first examination for certificates to practice medicine under the new rules promulgated by the State Board of Health requiring that the application be accompanied by a photograph of the applicant, was held at Kansas City, Dec. 29, 30 and 31, 1902.

X-Ray Not Compulsory.—In the suit of an employe against his employer for $20,000 damages for injuries alleged to have been received while in the employment of the defendant, Judge Gibson, Kansas City, has ruled that a court has no right or power to compel a person to undergo an *x*-ray examination.

Registration of Consumptives.—An ordinance providing for the registration of the name, address, sex and age of persons suffering from tuberculosis, within the limits of Kansas City, and regulating said matter was introduced in the city council and referred to the sanitary, hospital, etc., committee.

State Failed to Establish Fact of Practice.—The action of the State Board of Health in summarily rejecting an applicant for license to practice medicine has been decided to be an infringement of constitutional rights, and in the case in question, that of the State vs. Dr. F. A. Starbuck of Kansas City, Mo. and Kansas City, Kan., Justice Fairweather has found the defendant not guilty.

NEW JERSEY.

Bequest to Hospital.—Patrick Flanagan, Perth Amboy, who died recently in St. Michael's Hospital, Newark, has bequeathed his entire estate, valued at $7,000, to that institution.

Isolation Hospital Site Chosen.—The committee appointed to select a site for an isolation hospital for the Oranges, has secured a tract of 13 acres of pasture and wood land on the top of the First Mountain in West Orange.

Settled Out of Court.—The case of Dr. John R. C. Thompson, Bridgeton, against the Township of Downe, Cumberland County, for services rendered a smallpox patient, has been settled for $1,500. Suit was brought for $2,000, and a jury gave a verdict of $2,100.

Tuberculosis Sanatorium Site Secured.—The commission appointed to secure a site for the tuberculosis sanatorium has secured 550 acres of land at Glen Gardner, Hunterdon County. The commission is having plans prepared for extensive building thereon, and asks for an appropriation of $300,000 to carry out the plans. The last legislature made an appropriation of $50,000.

New Jersey Epileptics.—The annual report of the board of managers of the State Village for Epileptics, states that there are more than 2,500 epileptics in the state. It shows that 85 patients have been received at the village at Skillman since it was opened, in 1898, and that of this number 9 have been discharged as cured; 4 have been transferred to other institutions; 4 have been removed by parents; 2 have died, and 3 have escaped. During the past year 25 male and 20 female patients have been admitted, making the total population at the present time 75.

Hospital Staffs.—The medical staff of Somerset Hospital, Somerville, has reorganized by electing Dr. John P. Hecht, president, and Dr. Aaron L. Stillwell, secretary.——St. Michael's Hospital, Newark, has elected Dr. Herman C. Bleyle attending physician, and Drs. George H. Balleray, Paterson, Edgar Holden, Peter V. P. Hewlett, Charles J. Kipp, Charles Young, Charles M. Zeh and James Elliott, Newark, on the consulting staff.——The German Hospital, Newark, medical staff, has elected Dr. William F. Seidler, president; Dr. Frederick Hexamer, secretary, and Dr. William J. Roeber, treasurer.

NEW YORK.

New York City.

Gouverneur Hospital.—That this hospital has had a busy year is shown by the statement that the four physicians of the house staff have attended 57,721 cases in the dispensary, over 35,000 of which were surgical.

The Bulkley Lectures.—Dr. L. Duncan Bulkley began his usual winter course of lectures on diseases of the skin, January 7, at 4:15 p. m. The lectures will be held thereafter on every Wednesday afternoon in the out-patient hall of the New York Skin and Cancer Hospital, at the same hour, and are free to the medical profession.

Bellevue's New Superintendent.—Dr. William Mabon, formerly of Ogdensburg, took up his new duties as superintendent of Bellevue, Harlem, Fordham and Gouverneur hospitals January 1. After a tour of inspection of Bellevue, he expressed himself as well satisfied with the present state of affairs there, and disclaimed any intention of making any radical changes in organization or personnel.

Diet for City Institutions.—Commissioner of Charities Folks has found so much lack of variety in the dietaries of the institutions under his care that he has appointed, at a salary of $1,000 a year, Miss Florence R. Corbett, the present chief dietitian in the Kings County Hospital, as his assistant and adviser in the purchase, distribution and cooking of the food for the department. Miss Corbett is a graduate of the Kansas State Agricultural College.

"Million-Dollar Hospital" Wants Funds.—The Society of the Lying-in Hospital, better known as J. Pierpont Morgan's million-dollar hospital, has made an appeal to the public for funds for its maintenance. The hospital is intended to accommodate 186 persons, but at present only 62 beds are in use. The plea for help is based on the fact that all the other maternity hospitals of the city have a total of less than 600 beds, while the number of births in the Borough of Manhattan alone in the past year was 51,688, i. e., one child was born about every ten minutes.

Board of Coroners vs. Coroner's Physician Weston.—The Board of Coroners of the Borough of Manhattan have sought to try Dr. Albert T. Weston on various charges which they considered sufficient to warrant his removal, but he prevented such action by applying to the Supreme Court for a restraining writ. Justice Leventritt, of that court, has now decided that the Borough Board of Coroners, and not the whole city board, is competent to try Dr. Weston, and that the Manhattan board is right in its contention that Dr. Weston is not legally in the employ of the city, his term of office having terminated with that of the coroner who originally appointed him.

The New Hospital for Consumptives.—Allusion has already been made in these columns to the movement now on foot, under the auspices of the Charity Organization Society's Committee on the Prevention of Tuberculosis, for the establishment without the city limits of a new hospital for consumptives. It is estimated that, including the general hospitals, homes and sanatoria receiving tuberculous patients, there are accommodations in New York City for only about 1,000 consumptives. It has been estimated that one-eighth of all the deaths in the city are due to phthisis, and in Greater New York, in 1901, there were 8,141 deaths from this disease, while 13,387 cases of tuberculosis were reported in that year. This shows the inadequacy of present accommodations. The committee now has under its care 64 poor tuberculous persons.

Vital Statistics for 1902.—The annual report of the board of health, which has just been made public, shows a gratifyingly low death rate, not only for the whole city, but for each of the boroughs. The death-rate of New York City for 1902 was 18.74 per 1,000, which is considerably lower than any previously reported for this city, thus: In 1898 it was 20.26; in 1899, 19.47; in 1900, 25.97, and in 1901, 20.02. The total number of deaths for 1902 was 68,082, as compared with 70,803 for 1901. The death rate for the old city, i. e., the boroughs of Manhattan and the Bronx, was 19.49 for 1902. The nearest approach to this in the past was in 1899, when the death rate was 19.81. A popular belief, which is shared in to some extent even by physicians, that measles is a trifling malady receives a severe setback in the statement in this report, that the epidemic of measles in the first four months of last year caused an increase in the number of deaths over the year 1901 for the same months of 1,100. There was a slight increase in the number of deaths from typhoid, but this was offset by a decrease of 100 deaths from smallpox. There were 4,907 more births and 2,653 more marriages reported than in 1901.

Buffalo.

New Emergency Hospital.—A new accident hospital, called the Riverside Accident Hospital, has been opened in the Fitch Institute building, and a ward of eight beds is now ready for the reception of patients.

New Quarantine Hospital.—The councilmen have at last, by a bare majority, approved the resolution of the aldermen directing the commissioner of public works to prepare plans and specifications for a new quarantine hospital on the site of the present one on East Ferry Street.

Tenement-House Owners Ignore Law.—Health Commissioner Greene has submitted to the district attorney the names and addresses of 26 owners of tenement houses who have ignored the health department's orders to remedy the sanitation or other unsafe conditions existing therein.

Relief for Hospitals.—The committee on charitable institutions of the board of supervisors has granted financial aid to the following hospitals and dispensaries: Buffalo Eye, Ear and Throat Hospital, $2,000; Buffalo Eye and Ear Infirmary, $2,200, and German Hospital Dispensary, $1,700.

Eye and Ear Infirmary Report.—The twenty-sixth annual report of the Buffalo Eye and Ear Infirmary shows that during the past year 2,363 new cases were treated; of these 1,675 had diseases of the eye, 336 diseases of the ear, 260 diseases of the nose and throat, and 92 diseases of the skin. The total number of patients admitted since the opening of the institution was 37,786.

Fumigation of Mails.—Health Commissioner Green has written to Dr. Lewis of the State Board of Health of New York and to Dr. C. O. Probst, of the State Board of Health of Ohio, recommending that they take advantage of their authority to direct cities in which smallpox exists to fumigate outgoing mails. There has been a case of smallpox in Buffalo directly attributable to the mails. It occurred in a local mail handler sorting Rochester mail. A mail clerk was also taken from the train at Syracuse, N. Y., suffering from smallpox.

PENNSYLVANIA.

Sued for Suicide of Husband.—Mrs. Minnie Kincaid has sued the borough of South Bethlehem for $20,000 for the death of her husband, who hanged himself while quarantined with smallpox.

Alleged Illegal Detention.—Drs. Frank C. Gundlach and William C. Ranson, Pittsburg, are defendants in a damage suit of $5,000 for alleged illegal detention of Mrs. Tina Jackson on the grounds of insanity. It is contended by the plaintiff that the physicians took only a few minutes in making the examination.

Personal.—Dr. C. E. Boon, Johnstown, has been elected smallpox physician at a maximum salary of $300 per month. ——Dr. William A. Shannon, Ellwood, charged with being a public nuisance, because he did not report a case of smallpox to the secretary of the local board of health, was acquitted, Dec. 13, 1902, the county paying costs of suit.

The Fight Against Tuberculosis.—The Pennsylvania Society for the Prevention of Tuberculosis plans to organize the whole state into a system with a society of many thousand members. The hospital at White Haven is to serve as a center, and it is the purpose to establish like institutions and also dispensaries throughout the state. As to the system here adopted—out-door life with forced feeding—Dr. Flick states that he saw no better results abroad. The Pennsylvania system is more economical; the indigent poor are treated; and provisions are also made for dying consumptives, whereas European institutions care only for incipient cases.

The Care of the Insane.—A commission was appointed at the last session of the legislature to inquire into the condition of the insane of Pennsylvania and to suggest remedial legislation. The commission has visited all the institutions of Pennsylvania and the principal ones in New York, Michigan and Wisconsin. It is understood that it will recommend that all the institutions for the care of the insane be placed under a board of control having the right to buy supplies, transfer patients—keeping those susceptible of improvement apart from the violent cases—and to exercise a general supervision in the construction of buildings and in the appointment of attendants.

Philadelphia.

Coroner's Inquests.—The coroner has held within the year 2,745 inquests. There were 196 cases of suicide. Of these 42 were gunshot wounds, 33 gas asphyxiations, 32 strangulations, and 31 by the carbolic acid route.

Munificent Bequests.—The account of the executors of the estate of John D. Lankenan, who was for many years president of the German Hospital and the Mary J. Drexel Home, was recently adjudicated. The balance on hand for distribution is $1,139,777. Of many charitable bequests there are two of $569,888 each to the German Hospital and to the Mary J. Drexel Home.——A site for the new almshouse and insane department of the Philadelphia Hospital has probably been chosen. This is a matter of great concern to the profession in Philadelphia, and of vital importance to the laity on account of the overcrowded and antiquated equipment. The site determined on for the almshouse and insane department is ground of the House of Correction property at Holmesburg, where the city owns 150 acres of high, healthy, accessible, unoccupied land. On December 28, at the invitation of Mayor Ashbridge and the officials of the Department of Charities and Correction, a number of prominent physicians of the city made a visit of inspection to the proposed site. Resolutions were afterward unanimously adopted endorsing this site. After the meeting it was understood that Mayor Ashbridge will transmit a message to councils recommending the passage of an ordinance permitting the Department of Charities and Correction to use the site selected, and to begin at once the construction of the necessary buildings. This plan will permit the enlargement of the Philadelphia Hospital on its present site.

GENERAL.

Want Panama Canal Physician.—The American Association for the Advancement of Science petitioned the President, January 2, that one member of the Isthmian Canal Commission should be a physician.

To Kill Hawaiian Mosquitoes.—A crusade with oil to kill mosquitoes is begun in a part of Honolulu. The lowland taro-patches and swamps are an especial object of attack because of their standing water.

Hawaiian health reports for November showed that the unfavorable autumn weather caused in certain districts a large increase in influenza, pneumonia and dysentery. The general average of the reports made a favorable showing, however.

The Plague Conference.—In response to a request from nineteen states, Surgeon-General Walter Wyman has called a conference of the Public Health and Marine-Hospital Service with the health representatives of said states, to meet in Washington, D. C., January 19. This is the first conference called under the law of 1902 reorganizing the United States Marine-Hospital Service and providing for a conference of that service when requested officially by the health or quarantine officers of any five states. The principal object of this conference will be the consideration of bubonic plague now alleged to exist in some quarters of the United States and Mexico.

Estate of Major Walter Reed.—At a recent meeting of the New York Academy of Medicine, Dr. W. W. Keen, Philadelphia, said that he had been informed that the family of Major Surgeon Walter Reed had been left with only a very small pension for their support, and that President Gilman of the Carnegie Institute had suggested the propriety of the medical profession and the public generally raising for them a fund of $100,000. At the recent meeting in Washington of the American Association for the Advancement of Science, the medical and allied branches appointed a committee to collect a fund for Mrs. Reed.

CANADA.

Montreal General Hospital reports for December 241 patients admitted and 245 patients discharged; average daily sick in residence, 192; admissions to the outdoor departments, 2,556; deaths, 19.

New Wing for St. Michael's.—Two lots adjoining St. Michael's Hospital, Toronto, have been purchased, and the houses thereon will be remodeled and used as a maternity ward. Later a building will be put up. There are now 150 patients in this hospital, and patients have had to be turned away for lack of room.

Montreal Civic Hospital Problem.—The Montreal City Council has decided to give the Notre Dame Hospital and an English hospital each $15,000 a year for twenty-five years, if they will care for patients affected with contagious diseases. This hospital problem has been before the Montreal Council now for three years.

The Ontario death rate for 1902 from all causes is about that of 1901. For 1902, as compared with 1901, the figures are as follows: Diphtheria, 443—512; scarlet fever, 265—209; measles, 112—120; whooping cough, 145—112; typhoid fever, 332—345; tuberculosis, 2,205—2,286; other causes, 21,556—22,152. Totals, 25,058—25,736.

Smallpox Well in Hand in Ontario.—Dr. P. H. Bryce, secretary of the Ontario Board of Health, reports with the

close of 1902 that the smallpox outlook was much brighter than a year before. In December, 1901, 250 new cases were reported in the province while in December, 1902, but 86 were reported, and these were nearly all in two centers, one of which is now practically cleared up. During the whole year of 1902 there were in round numbers 2,500 cases, with 15 deaths. The year 1902 was the heaviest in this regard for a good many years. In 1901 there were 1,838 new cases and 7 deaths. In 1900 there were 11 deaths; in 1899, 7. Dr. Bryce was notified January 3 that smallpox had broken out at three points in Ontario, viz., Galt, in Waterloo County, Thamesville, in Kent County, and on the Desceronto Indian Reserve.

FOREIGN.

Antitoxin in Austria.—By order of the government of Austria, every drug store in that empire must keep diphtheria antitoxin on hand and sell it below cost.

Quarter Million for Hospital.—The London Hospital for Sick Children has received $240,000 from William Waldorf Astor to build a new out-patient department.

Laborde's Automatic Tongue Tractor.—A cable from Paris announces that Dr. J. V. Laborde has invented a mechanism to employ his resuscitation method by rhythmic traction on the tongue. It is electrically driven.

A typhoid serum was described, with reports of marked reduction of the death rate, at the International Medical Congress at Cairo. This will be reviewed in the Foreign Medical Literature department next week, title 55.

An international exposition of hygiene will be held at Buenos Ayres in April, 1904, in connection with the Second Latin-American Medical Congress. Several steamship companies have granted reduced rates for the transportation of exhibits.

Physicians on Mecca Pilgrimage.—The Egyptian government will have pilgrims from that country to Mecca go in a body with an escort of physicians to guard against the bringing back of the plague and to care for the health of the pilgrims on the trip.

Medical Honors for a Publisher.—The honorary degree of M. D. has been conferred by the university of Freiburg on the publisher, Gustav Fischer of Jena, who has brought out a large number of important medical books and collected works as well as medical periodicals.

The sleeping sickness, according to a report of the School of Tropical Medicine, London, is extending in Africa, and fears are expressed of its menacing Egypt. It has killed 25,000 people, chiefly in and about Uganda. It resembles meningitis and is almost invariably fatal.

Woman's Medical College at St. Petersburg.—Six years have elapsed since this college was established by the St. Petersburg authorities, and the first class to graduate has just received its diplomas. There were 111 members of the graduating class and the total number of students is now 1,314.

Argentine Antituberculosis Measures.—Instructions how to prevent the spread of tuberculosis have been printed on the match boxes used by a large match factory in the Argentine Republic. Our informant states that the pictures of the physicians most prominent in the crusade also adorn the boxes.

The "Vereinigung Alter Deutscher Studenten in America."—Our German exchanges welcome the birth of this new organization, of which Dr. Carl Beck of New York is the president. The aim is to promote closer intercourse and friendship between Germany and America in all matters pertaining to science, art and literature.

New Editors of Virchow's Archiv and Jahresbericht.—Professor Orth of Berlin assumes the publication of Virchow's *Archiv* henceforth, with Prof. O. Israel as editor. Professors Waldeyer and Posner are to continue the publication and traditions of Virchow's *Jahresbericht über die Fortschritte und Leistungen der gesammten Medizin.*

The plague in Mexico proves, on microscopic investigation, to be bubonic plague. People fled by hundreds from Mazatlan at first, but soldiers now prevent any emigration. The reports express the belief that the disease will not spread. U. S. Public Health officers are at the spot. Sanitation in surrounding cities is reported to be strenuous.

A Physician in the Ministerium of the Interior in Saxony.—Our German exchanges are rejoicing over the fact that a physician has been formally installed as a permanent member of the ministerium of the interior for Saxony. Dr. F. Renk has been selected for the post. He is a pupil of Pettenkofer and has long served as a member of the national council of health.

Fined for Assuming Title of Professor.—A charlatan at Hanover, Germany, had acquired the title of professor of music from some Italian school of music, and paraded this title of professor in all his advertisements and on his signs. The local court fined him $10 or to ten days' imprisonment for use of the title of professor as intended to deceive in regard to his medical standing.

Medical Correspondent in America.—Dr. Francis Munch has been sent to this country by the *Semaine Médicale* of Paris as special correspondent to write up the "*mouvement actuel de la science médicale*" in the United States. His first letter appears in the issue for December 24, and deals with Boston and Philadelphia, principally devoted to the work in radiotherapy by Williams, Ellis, Sweet and Rust.

Too Many Physicians.—The dean of the Paris faculty remarked at a recent meeting of the Academic Council that "families and teachers ought to dissuade young people from entering on a medical career unless possessed of independent means or exhibiting a very marked vocation for medical studies. There are too many physicians. This is very bad for the patients as well as for the physicians themselves."

Less Tuberculosis in Prussia.—The deaths due to tuberculosis were 31 to every 10,000 of the population in 1876; in 1891 the number was only 27; in 1896, 22; in 1901, 20. The number dropped from 36 to 22 in the cities, and from 28 to 17 in the rural districts. All the large cities show a diminishing death-rate from tuberculosis, and the decrease was apparent long before the sanatorium movement was inaugurated.

French National Subscription to Combat Tuberculosis.—An appeal has been issued by a committee of which Brouardel is chairman, calling on the people of France to subscribe toward a national fund for the erection and maintenance of sanatoria for consumptives. The appeal states that Germany now has 64 such sanatoria, sheltering 23,000 inmates, while France has only 2. It also states that during the last three years the German army has lost 1,300 men from tuberculosis, while France has lost 10,000 from this cause alone. An anonymous subscription of $50,000 has already been received.

Post-Graduate Facilities at Frankfurt.—The various medical institutes at Frankfurt a. M. are to be incorporated under the name of the Academy of Practical Medicine for the purpose of affording improved opportunities for post-graduate studies and research. A large sum has been raised for enlarging the present institutes and the city has appropriated funds to enlarge the hospital and establish an institute for anatomy and another for testing the purity of food supplies. Over half a million dollars has already been raised for the purpose in unofficial circles. The aim is to make Frankfurt an unparalleled center for post-graduate instruction.

The Eyelids in the Gore Case.—The cable reported the death of Ellen Gore in Paris from a bullet wound in the eye, and the arrest of the man who was alone with her at the time. The man has since been released on the sole ground that the lids and lashes of the eye penetrated by the bullet were intact. The medical experts, Socquet and Brouardel, testified that there was every probability that the injury was due to an accident, as the victim of an attempt to murder would naturally close the eyelids, or at least they would flutter more or less. The fact that they were intact in this case, they said, indicated that the victim was tranquil at the moment the ball struck her.

The Fifth International Congress of Applied Chemistry will begin its sessions in Berlin, May 31, 1903. The sections are as follows: Analytical chemistry, apparatus and instruments; chemical industries of inorganic products; metallurgy, mining and explosives; chemical industries of organic products; sugar industry; fermentation and starch manufacture; agricultural chemistry; hygienic, chemical and pharmaceutic chemistry; photochemistry; electrochemistry and physical chemistry; legal and agricultural problems in connection with the chemical industries. Dr. H. W. Wiley, chief of the Bureau of Chemistry, Department of Agriculture, Washington, D. C., chairman of the American committee, will give further information to those desiring it.

Prizes for Research on Fish Poisons.—As a number of cases of poisoning from the consumption of raw salted fish occur every year, the Russian authorities have offered prizes of $2,600, $800, and $530, for the best work on the nature of the poisonous substance, its action on the animal body, means

of preventing its formation, diagnosis, and the antidotes for it, and for poisoning from food in general. The smaller prizes will be awarded for the best work on any one or more of the above branches of the subject. All communications must be addressed to the "Ministère de l'agriculture et des domaines," St. Petersburg, and be received before Oct. 3, 1903. They may be in English, French, German, Latin or Russian. A similar prize was offered five years ago, but there were no contestants.

The French Pharmacists' Oath.—The Paris Pharmacists' Syndicate recently sued a pharmacist for illegal practices. His defense was that he was not a legal pharmacist and that there was not a single legally qualified pharmacist in France, as none of them had taken the oath which was established in the fourteenth century as an indispensable qualification. The oath has eighteen paragraphs; in one the pharmacist vows never to dispense an abortifacient or to practice abortive measures; never to substitute for any ingredient in a prescription without the advice "of some one wiser than I"; never to give a purge to a person sick with any acute disease, without previously consulting with some physician, and to contribute in every possible way to "the honor, the glory, the ornament and the majesty of medicine." Centuries have passed since this oath was exacted, and the pharmacist's defense was not accepted.

Further Progress in the Sanatorium Movement in Germany.—The sick benefit society which includes the district of Berlin has sent a circular to the employers of wage earners calling their attention to the new sanatorium at Beelitz and urging them to inform their workmen and workwomen that free accommodations are offered to all working people suffering from chronic affections such as neurasthenia, anemia, gastric disorders, bronchial catarrh, rheumatism, gout, debility after acute diseases, etc., in case their affection offers the prospects of a cure after a four to six weeks' course at the sanatorium. It is especially urged on wage earners still at work, but feeling the inroads of a chronic affection, who might be completely re-established by a course at the sanatorium. During the absence of the breadwinner at the sanatorium a weekly sum will be paid to his family. Employers are asked to use their influence to have their employes take advantage of the offer.

Prizes Distributed by Paris Academie de Medecine.—Only 22 of the 38 prizes offered were awarded, and the practice of dividing certain prizes has been discontinued on request of the executors of the endowments. Bezançon and Griffon were given 2,000 francs out of the Audiffred fund for their research on the cultivation of the tubercle bacilli in gelosed blood. Castaigne also received a prize of 2,300 francs for his methylene blue test of the permeability of the kidneys. A prize of 5,000 francs was bestowed on Jaboulay of Lyons for his "Surgery of the Nerve Centers, Viscera and Members." Cavazzani of Ferrara received a prize of 1,200 francs for research on the vasodilating center for the vessels of the brain. Ehlers of Copenhagen and Cohnheim of Dresden received a prize of 1,500 francs for their study of leprosy in Crete. Testut of Lyons also received a prize of 4,400 francs for his "Manual of Anatomy." No communications were received in competition for seven of the prizes. Among the medals awarded was one to Dr. G. Ullman of Chester, Pa., for his work on vaccination. He is a graduate of the Medical School of the University of Paris.

Dangers of Hypnotism.—A suit has recently been decided in Germany which has attracted much attention. Winkelmann of Berlin gave an entertainment of hypnotism at Insterburg, with the consent of the authorities. Among his subjects was a youth named Lau, who had always been very nervous. The other subjects showed no disturbances from the hypnotic suggestion, but young Lau became much excited, gasped for air after the seance, and was mentally unbalanced to such a degree that he had to be under restraint for four months. Although at present dismissed from the sanatorium, he is still incapable of entering business, and his family sued the "suggestor" for damages. The court, while recognizing that the possibly latent nervousness of the young man had been fanned into actual insanity in all probability by the hypnosis, yet the defendant had evidently not intended such a result, as he practices this means of livelihood under the eyes of the municipal and medical authorities. As the former had granted him permission to give the entertainment, notwithstanding the knowledge of his lack of special training, the charge against him was dismissed.

German Society for School Hygiene.—The sanatorium treatment of tuberculosis in Germany is for the benefit of adults. Children have not been regarded hitherto, while France has accommodations for 1,200 in its seashore children's sanatoriums. In the November meeting of the German Society for School Hygiene, Baginsky pointed out that scrofulous and tuberculous children should be classified as: 1, those with inflamed glands, eruptions and catarrhal inflammations; 2, those with actual but not open tuberculous lesions of bones, glands, or joints; 3, with open lesions of this kind, and 4, those with pulmonary tuberculosis. The anemic children of the first group require merely to be placed in a more favorable environment. Those with pulmonary lesions should be placed in a sanatorium for lung diseases, but the others are best treated in a seashore sanatorium. Experience teaches, he states, that bone and joint tuberculous lesions frequently heal without the necessity for an operation under the influence of the sea air. Other speakers mentioned that the climate of France was more favorable for the purpose than that of Germany, and Orth urged the erection of a seashore sanatorium at Naples or at the Madeiras. A committee was appointed to discuss ways and means.

LONDON LETTER.

Paraffin Injections for Nose Deformities.

Gersuny's method of treating deformities of the nose by paraffin injections has not been long adopted in England, but so far the results have been satisfactory. At the Clinical Society Mr. S. Paget read a paper on 25 cases, which is important in consequence of certain suggestions in technic. In his earlier cases he used Eckstein's paraffin, but he found that it has obvious disadvantages and no advantage over paraffin melting at a temperature of 25 or 30 F. lower. The best melting point he finds is between 108 and 115 F; he now uses paraffin melting at 111. Of many syringes he finds Eckstein's is the best: it keeps the heat well, can be easily worked with one hand and has a screw nut on the piston, which prevents any sudden running in of the paraffin, but it ought to have a short and strong steel needle. He thinks it is wrong to attempt to raise the skin with a tenotomy knife before injection, but if there has been exfoliation of bone so that a depressed and adherent cicatrix is produced it may be advisable to free the skin at this point. He emphasizes the fact that paraffin shrinks when it sets; and the paraffin that sets the hardest shrinks the most. The inevitable shrinkage may be so slight as to be hardly visible; it involves the addition about a week later of a few more drops of paraffin under cocain.

Syphilis and Life Assurance.

At the Edinburgh Medico-Chirurgical Society Dr. Byron Bramwell read an important paper on this subject. He regarded the life of a man who had syphilis as a damaged one, and did not think that an office should accept him as a first-class life, but should impose an "extra." Of course there were some exceptions. The statistics of assurance companies afforded no evidence as to the mortality from syphilis, and as to its effects on longevity. To arrive at some sort of an estimate —necessarily an underestimate—he picked out from such statistics the diseases due in a large proportion of cases to syphilis—tabes, general paralysis, and aneurism. Death due to syphilis is almost always the result of a tertiary lesion. Hence the importance of the date at which tertiary lesions develop. In 107 cases of grave cerebral and spinal syphilis 12.1 per cent. occurred in the first year, 40 per cent. during the first 5 years, and 68 per cent. during the first 10 years after infection. Probably tertiary lesions occurred in 10 per cent. of all cases of syphilis. Most observers seemed to think that the mortality from syphilis was almost entirely the result of typical tertiary lesions, but probably only a small portion was. A much larger proportion was due to aortic aneurism, aortitis and resulting aortic incompetence, and to para-syphilitic lesions (general paralysis and tabes), cirrhosis of the liver and arterial disease. In 32 cases of tabes the average duration of the disease was 8.8 years. In 17 of these, in which the exact date of infection was determined, the expectation of life was diminished by 270 years, or an average of 15.8 years. As to general paralysis of the insane, and it generally lasted from 2 to 6 years, the average age at death was 44 years. As to aortic aneurism it was an underestimate to ascribe 50 per cent. of the cases to syphilis. Applying these estimates to the Scottish Widow's Fund, of 3,658 deaths, 6 were due to tabes, 52 to general paralysis of the insane, and 24 to aortic aneurism. Granting that 75 per cent. of the deaths due to the two former diseases and 50 per cent. of those due to the latter disease were the result of syphilis, this gave 55.5 deaths. But in addition many cases of aortic valvular disease and some of cirrhosis of the liver and kidney were no doubt due to syphilis. Moreover,

there were doubtless some deaths certified as cerebral softening, apoplexy, hemiplegia, insanity, myelitis, paraplegia, atheroma, sclerosis of the coronary arteries, angina pectoris, myocarditis, laryngitis, etc. Finally the persistent and widespread effects of syphilis render it probable that the disease causes arterial degeneration and premature senile changes. All these considerations lead to the conclusion that the longevity of syphilitics, apparently healthy when they presented themselves for examination, was on an average shorter, probably considerably shorter, than it would have been if they had not had the disease.

Typhoid Fever from Contaminated Oysters.

A number of cases of typhoid fever have occurred at Portsmouth and Winchester, which are believed to be due to oysters taken from beds contaminated with sewage. The dean of Winchester has just died from typhoid fever, believed to have been contracted in this way, and among the victims is Dr. England, formerly surgeon to the Royal Hampshire County Hospital. At Southampton, also, 8 cases have occurred. A scare has been created in London, and the oyster merchants have sent circulars to the medical officers of health in localities in which there are oyster beds requesting reports. Those from the non-incriminated ones have been satisfactory.

Mr. Hutchinson's Leprosy Investigation in India.

At the Polyclinic Mr. Jonathan Hutchinson, who is about to go to India on a tour of investigation, read a paper on the present state of the leprosy question in connection with the Prince of Wales' Leprosy Fund. He said that he first planned the tour he was about to undertake 30 years ago. In the interval he had read everything which has come to hand on the subject of leprosy, and taken the evidence of a large number of the medical men, missionaries, and others who have resided in India. Through the whole of this period he has held firmly the conviction, which has strengthened as years has advanced, that leprosy is in the main a food disease; that it spreads only to a small extent by personal contagion, and that the one article of food which is to be suspected is badly-cured fish, eaten without its being sufficiently cooked. In all ages, and in almost every country where leprosy has prevailed, the popular belief has been that fish eating is in some way connected with it. The way in which the disease has waned and ultimately almost ceased in Europe with advancing civilization is in harmony with this belief. It advanced in inland districts of Europe with the advance of Christianity, and the observance of fish fasts, and it disappeared when Protestantism threw these fasts into disuse. Other influences are the development of agriculture and the increased production of other kinds of food. Norway and Iceland have always been conspicuous for the prevalence of the disease. The former has from time immemorial had the largest fishing trade in the world, and of the latter an old geographer wrote that it ought to be named "stock fish." In both of these places fish is still largely consumed. Over the whole world at the present day the prevalence is almost in ratio with the use of cured fish. Leprosy is not very prevalent on the main land of India. The average prevalence in India, South Africa and Norway is something less than 5 per 10,000. In Ceylon it does not reach 2 per 10,000; but in some of the smaller islands off the coast of India—Minicoy, for instance—where fish is eaten by the laboring population three times a day, its prevalence reaches the enormous ratio of 100 or 150 per 10,000. Among Mr. Hutchinson's more important inquiries will be the question whether the statements made by certain Hindus and Brahmins that they have never eaten fish are trustworthy.

Correspondence.

Beri-Beri in Louisiana.

ABBEVILLE, LA., Dec. 22, 1902.

To the Editor:—The history of this disease dates back many years, occurring principally in the Orient, along the coast of China and Africa. I have been unable to get much information on the subject. A short article appeared in THE JOURNAL, if I remember correctly, concerning it some time ago. In no work on practice or in any medical literature am I able to find a record of a single case occurring in Louisiana. Still, that this disease exists here has been proven beyond a question of reasonable doubt in my mind as well as in the minds of several physicians of prominence in southwest Louisiana. We have had many cases in our practice during the last five years.

As to its causes there seems to be little known. Some writers claim that beri-beri is due to a parasite, others to certain miasmatic germs developed in tropical climates, others claim that it is due to the eating of rice, which *per se* generates it, and still others claim the micrococcus is in the rice. This latter condition seems to have some bearing on the causation of the disease as it exists in Louisiana at the present date.

In the last fifteen years, southwest Louisiana—which up to that time had raised only a few barrels of rice—has developed this industry enormously, and we have now in this, Vermilion Parish, and several surrounding parishes, miles and miles of nothing but rice; so much so that we now raise in this part of the country more rice than is raised in all of the other states. What was a few years ago barren prairies, low, alluvial soil, and filled with wild cattle, is to-day a prosperous country occupied by industrious farmers raising virtually nothing but rice, which has proved very profitable to them. They have made it a sure crop by irrigation from deep wells and large sub-surface canals.

I have been practicing medicine in this parish for twenty-three years and up to five years ago never saw a case of beri-beri, nor anything resembling it. Since then, however, there have been in this district no less than forty cases of a disease which we have termed beri-beri.

Dr. Robert J. Young of this town has treated in the last five or six years nearly thirty such cases. Dr. C. J. Edwards, same town, has treated perhaps a half dozen or more. Dr. W. G. Young of Crowley, La. (the center of the rice district), has seen about the same number, and I have had seven or eight. The cases have occurred, without exception, in a locality surrounded by rice fields, and all the patients were heavy eaters of rice. Most of the patients gave a history of having had a slight chill, followed by a low febrile condition for about two days, profound prostration, loss of appetite, generally constipation, insomnia in the majority of cases, rapid heart action, anemic murmurs, anasarca, inability to lift the feet and when walking they moved their feet with a great deal of difficulty, and would invariably drag their legs as if from partial paralysis. In all of these cases there was multiple neuritis and in certain portions of the body, especially in the legs, anesthesia. While the patients were very apprehensive of their condition, not one case died. All recovered slowly under proper treatment. Some were sick several months before becoming once again their former selves.

All the physicians named and myself used similar treatment, which consisted of: If possible, a change of locality, baths, a good nutritious diet with plenty of milk, medication consisting of calomel and soda, cholagogue cathartics, followed with such as digitalis, convalaria, strophanthus, spartein and especially strychnin, which was kept up through the entire treatment in heavy doses, tr. fer. mur, and arsenic. Quinin seemed to have no effect.

These cases seem to occur always—we might say endemically—all within a radius of about twenty miles, and all came under my observation within a period of twenty-four months. Since then we have failed to see others.

FRANK FENWICK YOUNG.

NOTE.—A report on beri-beri by a Norwegian committee was published in THE JOURNAL of August 16, xxxix, p. 388. Abstracts of an interesting discussion on the same subject at the last meeting of the British Medical Association, published in the *British Medical Journal*, Sept. 20, 1902, appeared in THE JOURNAL on p. 941 of the same volume. The rice theory of the disease suggested by our correspondent was upheld in the discussion by Rost, whose views, as given in a paper previously published, will be found in the issue of THE JOURNAL for August 23, p. 454.—ED.

A Side Light on Ethics.

BURLINGTON, IOWA, Jan. 5, 1903.

To the Editor:—During the past year or two I have read in THE JOURNAL and other medical publications a good deal about "organization," "ethics" and "reciprocity," and I have even written a few lines on these subjects, which have found their

way into print; but I have seen nothing which so completely sums up the whole matter as Dr. Gillmore's letter in your current issue. Until we can get ethical unification—a oneness of purpose individually and collectively—it seems to me useless to talk about organization and reciprocity; and through one thing and another, mostly perhaps as Dr. Gillmore suggests, the absence of emphasis on the golden rule in the teaching course, we seem to be drifting farther and farther from this unification.

I do not wholly agree with Dr. Gillmore that commercialism is a basic fault. It may be difficult to harmonize commercialism with the golden rule; but as we must all be more or less commercial so long as we charge fees and send out bills for services, we should certainly make the effort. And if we only succeed in harmonizing the Chinese version: "Do not do unto others that which we should not like them to do unto us," the situation would be vastly improved. Truly yours,

H. B. YOUNG.

DETROIT, Jan. 3, 1903.

To the Editor:—I ask permission to add my approval to the wise, just and timely "thesis" under the above title by Dr. Robert T. Gillmore, which appeared in your issue of January 3.

In his communication the Doctor has so ably covered the ground that there is very little left for those who agree with him to say except to express their approval and add their sincere "Amen."

Those, if there are any such, who are disposed to differ with the Doctor's views are not likely to present their arguments either in the columns of THE JOURNAL or elsewhere. I have heretofore given such expression as I could to the feeling of shame and regret with which the commercial spirit at present animating and overruling our profession has affected me. Consequently Dr. Gillmore's presentation of the subject afforded me sincere gratification. With medical students and young physicians I have had an extensive and intimate acquaintance, and that I have been known as their friend will, I believe, be universally admitted. Nevertheless it has been my painful duty to preach "in season and out of season" against their openly-avowed passion for converting, with unseemly haste, their scientific and technical acquirements into filthy lucre, the first and most important question as to the essential nature of a case being too often "How much money is there in it?" instead of "What can I do for the best interest of this patient, and what can I learn from a careful study of the case?"

This spirit of commercialism exhibits itself in many ways, and unquestionably exercises a deleterious effect on the youthful aspirant, while at the same time it has a natural and inevitable tendency to prejudice against him "those seniors who by their labors have contributed," etc.

Many years of close observation have tended to convince me that few greater misfortunes can befall a young practitioner than too rapid success in the acquisition of practice and the premature growth of his bank account. It would appear, therefore, that the necessity for reform and improvement is not limited entirely to either one of the parties involved.

At any rate, there can be no room to question Dr. Gillmore's fundamental deduction: "If we are not content with the present condition of affairs we must begin at the very beginning. We must impress on the applicant for admission to our medical schools that something more is required of him than his fee, and satisfactory credentials as to his literary attainments. He must be capable of comprehending and appreciating the sentiments and essentials of the golden rule."

On the shoulders of his teachers must of necessity rest the vital responsibility of imbuing his youthful nature with so much of genuine devotion to science as will have the effect of overshadowing and crushing out in reasonable measure the deplorable spirit of commercialism. His study of ethics will then become a real labor of love, the actual practice thereof second nature, and his life's motto will be appropriately set forth in the words of old Polonius: "To thine own self be true, and it must follow e'en as night the day, thou canst not then be false to any man."

DONALD MACLEAN.

State Boards of Registration.

Maine.—The Maine Board of Registration of Medicine, according to the report of the examination held at Portland, November 11, 1902, sent by Dr. A. K. P. Meserve, secretary, examined in 7 subjects, by 70 questions. The percentage required to pass was an average of 75 and of not less than 60 in any one branch. The examination was written; 7 were examined, 6 passed, and 1 failed.

PASSED.

Clippings from Lay Exchanges.

FLUENCY A DESIDERATUM.

"Dr. —— has recently come to this city. . . Dr. —— is a German, speaking that language fluently, which will be appreciated by those of that nationality. . . ."—*Baraboo* (Wis.) *Republic.*

DISORDER OF AORTIC ARTERIES.

"—— dropped dead. . . . in the office of Dr. ——. Dr. —— performed an autopsy and found a disorder of the aortic arteries which ceased to feed the heart."—*Milwaukee* (Wis.) *News.*

ONE DOLLAR ADMISSION.

Euclid.—"Dr. —— has been fixing up a suite of rooms over the store for office purposes. They are large bright and cheery, and almost make one want to be a little sick so as to call on him and enjoy their brightness. One dollar only, will give any one that privilege."—*Crookston* (Minn.) *Farm Journal.*

Tentative Diagnosis.—Nothing has a greater tendency to increase a man's skill in inductive reasoning than the habit of writing down, after each examination, the diagnosis that seems to him most likely, no matter how many question-marks he puts after it, nor how frequently he changes this diagnosis at subsequent examinations. The very necessity of putting in concrete form what is too often a hazy idea, sharpens the faculties and stimulates the mental processes.—*Phila. Med. Jour.*

The Eye Should Have a Broad Range.—One should have the opportunity of seeing a long distance. We are denied this opportunity. We are hemmed and hedged in until the distance we are capable of seeing is very short indeed. This is why I am a strong advocate of parks, of promenades. Green is naturally a restful color, and if the city could be provided with long avenues and splendid parks, where one's eyes could stretch out in a long vista, it would be a great thing.—Quoted from an optician in *New Orleans Times-Democrat.*

Curability of Tuberculosis of the Pharynx.—Veis describes five cases of tuberculosis of the pharynx, isolated and primary in one, and accompanied by insignificant pulmonary lesions in the others. He succeeded in curing them all by local treatment, for which he recommends a concentrated solution of trichloracetic acid. Improvement was manifest in his cases, which were all ulcerative, after the first application of this acid, under which the tissues turned white. The cauterization can be repeated every four or five days until complete cicatrization.—*Arch. f. Laryngol.*, xii, 3.

The Nobel Prizes.—Considerable disappointment is being expressed, says the *Allg. Med. Ct.-Ztg.*, that the executors of the Nobel estate are not carrying out to the letter the wishes of the testator in regard to the prizes awarded. The will stipulated that the achievements for which the prizes are to be bestowed should be recent. This stipulation applied to the work of Ross, but not to that of Fischer, who received the chemistry prize. His fame rests on his synthesis of the various kinds of sugars, and similar works many years ago. The physics prize was divided between Lorentz of Leyden and Zeemann of Amsterdam, who first announced the discovery that optic phenomena could be influenced by magnetic action. The prize for literature was given to Mommsen, whose great historical work dates from fifty years back. The testator evidently intended to encourage and sustain struggling investigators rather than to reward persons already resting on their laurels.

Book Notices.

STUDIES FROM THE DEPARTMENT OF PATHOLOGY OF THE COLLEGE OF PHYSICIANS AND SURGEONS, Columbia University, N. Y. Vol. VIII. For the Collegiate Year 1901-2. Paper.

With the apparent exception of the first article on the "Morphology of Ganglion Cells in the Rabbit," this volume is made up of reprints from various medical journals, all of them duly credited with the source of their first appearance. The director says, in his preface, that it seems that this form of publication—first, the wider circulation which current medical journals afford, and the subsequent grouping together of reprints—would more certainly fulfill the aims of such studies than would a separate department or university publication. The only objection we have to offer is that the difference in type, margin or pages, etc., makes a very clumsy arrangement. This, however, is only a minor objection. The book is a valuable collection of important monographs on the subject considered.

A TREATISE ON THE DISEASES OF THE EYE, NOSE, THROAT AND EAR. For Students and Practitioners. By Various Authors. Edited by William Campbell Posey, A.B., M.D., Professor of Ophthalmology in the Philadelphia Polyclinic; and Jonathan Wright, M.D., Attending Laryngologist to Kings County Hospital. Illustrated with 650 Engravings and 35 Plates in Colors and Monochrome. Cloth. Pp. 1238. Price, $7.00. Philadelphia and New York: Lea Brothers & Co. 1902.

One's first impression of this book is that the color of the binding is abominable. It is positively displeasing to the eye, whether the book is viewed by itself or with other works on the shelves of one's library. We certainly trust that the future editions will appear in a more rational dress.

It is an octavo volume of 1238 pages, 685 of which are devoted to the eye, 386 to the nose and throat, and 128 to the ear. It is well printed on good paper, which, fortunately, is not so glossy as much of the highly calendered paper used in modern text-books and magazines. Most of the

colored plates and illustrations are admirable, but a few are so bad that we wonder at their being used. It is impossible to convey an adequate idea of the extent and scope of the work without giving the table of contents, which follows:

THE EYE. Examination of the Eye, by William Campbell Posey, M.D. The Physiology of Vision, by William Norwood Suter, M.D. Refractive Errors in General, by Alexander Duane, M.D. The Motions of the Eyeball and Their Derangements, by Casey A. Wood, M.D. Diseases of the Orbit, Lachrymal Apparatus, and Lids, by R. A. Reeve, M.D. Diseases of the Conjunctiva, Cornea, and Sclera, by John E. Weeks, M.D. Embryology of the Eye: Anomalies, Diseases, and Injuries of the Iris, Ciliary Body, Choroid, and Vitreous, by H. V. Würdemann, M.D. Sympathetic Ophthalmia, by H. Gifford, M.D. Diseases of the Retina, Optic Nerve, and Its Cerebral Origin, by T. Holmes Spicer, F.R.C.S. Eng. Diseases of the Crystalline Lens, by Edward C. Ellett, M.D. Glaucoma, by E. Treacher Collins, F.R.C.S. Eng. Disturbances of Vision without Apparent Lesion, by Elmer G. Starr, M.D. The Eye in Its Relation to General Diseases, by C. F. Clark, M.D. General Preparation for Operations on the Eye, by Clarence A. Veasey, A.M., M.D. The Technique of the Pathological and Bacteriological Examinations of the Eye, by Edward A. Shumway, B.S., M.D.

NOSE AND THROAT. The Histological Pathology of Diseases of the Nose and Throat, by J. L. Goodale, M.D. Methods of Examination; Instruments and Apparatus and Their Use, by J. E. Newcomb, M.D. Inflammatory Diseases of the Upper Air Passages; Hay Fever; Rhinorrhea; Asthma; Influenza, by Charles W. Richardson, M.D. Diphtheria of Nose and Throat; Intubation; Syphilis, Tuberculosis, Lupus and Leprosy of Nose and Throat; Chronic Laryngeal Stenosis; Foreign Bodies in Nose and Throat; Rhinoliths, by William Kelly Simpson, M.D. Neoplasms of the Nose and Larynx; The Local, Medicinal, and Surgical Treatment of the Larynx, by W. E. Casselberry, M.D. Diseases of the Accessory Sinuses, by St. Clair Thomson, M.D., F.R.C.S., Eng. Diseases of the Oropharynx and Nasopharynx, by H. S. Birkett, M.D. Neuroses of the Nose and Throat, by Emil Mayer, M.D. External Deformities of the Nose; Cleft Palate, by F. E. Hopkins, M.D.

THE EAR. Examination of the Ear; Diseases of the External Ear; Diseases of the External Auditory Meatus; Otomycosis; Foreign Bodies; Wounds of the Membrana Tympani, by F. E. Hopkins, M.D. Diseases of the Internal Ear and Auditory Nerve; Deaf Mutism, by E. A. Crockett, M.D. Purulent Inflammation of the Middle Ear, by Henry Arnold Alderton, M.D. Chronic Non-Suppurative Middle-Ear Disease, by Arthur H. Cheatle, F.R.C.S. Eng.

The names of the authors are a sufficient guarantee that the subjects assigned have been well treated, and that the matter has been brought down to date. Each writer has covered completely the topic assigned, thus avoiding the repetitions and contradictions common to systems. As a rule, the articles are clearly and concisely written, and the book as a whole will be appreciated by the general practitioner, and at the same time the undergraduate will find nearly all the information he needs on these subjects and more than he has time to master. Although it enables the reader to become familiar with the style of many and to relax or concentrate his attention, according to the perspicuity of the individual writers, yet we confess to some disappointment in reading almost all of these composite works on account of the distraction caused by the various styles. In other words, it appears to us much easier to grasp and to retain the meaning when a single style, even though not altogether to our liking, pervades a book from cover to cover. The chapter on the relation of the eye to general diseases will be of special interest to the general practitioner, and that on the pathology of diseases of the throat, nose and ear will be found instructive even to the specialist. There is so much to praise in this work and so little to criticise one dislikes to make an adverse criticism. We imagine, however, that many oculists will be astonished on reading the chapter on refraction by Dr. Doane. On page 98 he says, "A certain amount (0.25 to 0.50 D.) of primary astigmatism may be regarded as *physiological* in that at least that amount is found in nearly every eye." And also, on page 131, "Astigmatism of only 0.25 or 0.50 D. I do not prescribe for, unless the symptoms (asthenopia, blurring of sight, etc.) seem particularly to call for the correction, or unless the patient has to use his eyes for very close and continuous work, or finally, unless the patient is going to use a glass anyhow, in which case I regularly add the cylinder correction that he requires, however small." It seems very difficult to reconcile these statements with the fact that many patients of many oculists are securing complete relief from distressing headaches by wearing constantly the correction for 0.25 and 0.50 D. of astigmatism.

PSYCHOPATHOLOGICAL RESEARCHES. Studies in Mental Dissociation with Text Figures and Ten Plates. By Boris Sidis, M.A., Ph.D., Director of the Psychopathological Laboratory. Published under the Auspices of the Trustees of the Psychopathic Hospital, Department of the New York Infirmary for Women and Children. Cloth. Pp. 329. Price, $3.00 net. New York: G. E. Stechert. 1902.

This may be considered as a sort of posthumous publication of the New York State Pathologic Institute. The institution still exists, but under other management. This is a publication of a research in a line which has possibly and apparently been discontinued by that institution. This is not said in disparagement of the institute, for we have no doubt under its present management its work will be as useful in the future as in the past, though under other direction and with a somewhat different policy. The book consists of a clinical narration of cases, with special relation to the functional and organic nervous pathologic states, and will be of interest to the psychologist and neurologist, though hardly so to the general practitioner, notwithstanding its narration of cases which would have a certain amount of interest. The conclusions of most interest as regards these dissociated states in psycho motor and psycho-pathologic conditions are those as regards the relation of functional to organic disease, and especially the nature of so-called psychic epilepsy, which the author considers sometimes a functional neurosis. The book is published under the authority of the trustees of the Psychopathic Hospital Department of the New York Infirmary for Women and Children, and another work on Principles of Psychology and Psychopathology is promised to appear soon.

A MANUAL OF MEDICAL TREATMENT OR CLINICAL THERAPEUTICS. By I. Burney Yeo, M.D., F.R.C.P., Emeritus Professor of Medicine in King's College, London. Tenth Edition. Fifteenth Thousand. Two Volumes. Cloth. Pp. 696. Price, $5.00. Chicago: W. T. Keener & Co. 1902.

The value of this work is clearly shown by the demand. The author includes in Volume I the therapeutics of the diseases of the organs of digestion, the heart and blood vessels and of the blood and ductless glands, diseases of the respiratory organs, including a chapter on the prophylaxis and sanatorium treatment of phthisis, which is concluded in Volume II. The treatment of erysipelas and of hay fever has received additional consideration in Volume I, in which chapters the experience of American authors has been properly recognized. In Volume II the author discusses the treatment of diseases of the liver, urinary and renal affections, nervous system, constitutional diseases and specific infective diseases. Additional subjects also receive consideration which have not been considered in previous editions, such as paralysis agitans, cerebral tumors, cerebrospinal fever, rachitis, scurvy and purpura. The author treats the different subjects from the standpoint of the disease and gives a thorough outline of the general treatment of the disease, prophylactic as well as medicinal, and then considers the complications individually. Formulæ are appended to each chapter which are adapted to the different stages of that disease. The principal fault of the work is that some of the formulæ contain ingredients taken from the British Pharmacopeia which do not occur as standard preparations in American materia medicas. But the large experience of the author in therapeutics is embodied in these volumes in such a manner as to render them the peer of anything in the line of treatment.

THE MEDICAL RECORD VISITING LIST OR PHYSICIANS' DIARY FOR 1903. New Revised Edition. Leather. Price, $1.25. New York: Wm. Wood & Co. 1902.

This is one of the standard visiting lists and one of the best. The volume for 1903 has been considerably improved. It contains a mass of information in a very small space, besides the usual well-arranged blank pages for records of visits, etc.

Marriages.

W. A. HOLLIS, M.D., to Miss Aldah Leach, both of Hartford City, Ind., December 24.

S. S. MYERS, M.D., to Miss Joycie P. Weaver, both of Centreville, Kan., November 26.

ERNEST LAPLACE, M.D., to Miss Katharine Borsch, both of Philadelphia, December 16.

ALFRED J. STOCKER, M.D., Erie, Ill., to Miss Nettie Stratton, at Belleville, Ont., December 4.

J. LOUIS C. PERRILLIAT, M.D., to Miss Marie Louise Caiborne, both of New Orleans, December 9.

JOSEPH JAMES HARRISON, M.D., to Miss Edna Earl Goans, both of London, Tenn., December 23.

PHILIP SCHUYLER DOANE, M.D., to Miss Helen Pullman Stewart, both of Chicago, January 1.

ELWIN O. CHURCH, M.D., Henry, S.D., to Miss Ethel Feay Davison of Kampeska, S.D., December 25.

THOMAS OVERTON BURGER, M.D., to Miss Hallie L. Bellamy, both of McMinnsville, Tenn., December 17.

FREDERICK S. BOWEN, M.D., Woodburn, Iowa, to Miss Agnes Sullivan of Newburgh, N. Y., December 21.

CARL I. SULZBACHER, M.D., Kansas City, Mo., to Miss Decimond Minor of Chillicothe, Mo., December 11.

PHILIP GIBSON GARY, M.D., Wakeman, Va., to Miss Laura Irene Robbins of Lester Manor, Va., December 23.

ARTHUR BUCKNER HARRIS, M.D., Cannelton, W. Va., to Miss Caroline B. Lyons, at Charlottesville, Va., December 23.

ALFRED AUSTIN BECKER, M.D., Jamestown, N. Y., to Miss Maude Jane Burch of New Richmond, Pa., December 24.

DAVID T. MUIR, M.D., Alden, Kan., to Miss Harriet M. Peters of Petersburgh, N. Y., at Kansas City, Mo., December 24.

GEORGE MILTON BOYER, M.D., Washington, D. C., to Miss Annie Marie Bowman of New Gaithersburg, Md., December 24.

HARRISON C. HOPPER, M.D., Galesburg, Ill., to Miss Clementine Van Ravenswaay of The Hague, Holland, at Booneville, Mo., December 25.

Deaths.

Dennis J. Loughlin, M.D. Jefferson Medical College, Philadelphia, 1881, formerly city commissioner for the Moyamensing District; member of the state legislature; appraiser of drugs at the port of Philadelphia, etc., died at his home in that city, December 27, from Bright's disease, after an illness of three months, aged 55.

William Stenning Harding, M.D. Edinburgh, 1836, in active professional life in St. John, N. B., until a few years ago, and until 1895 medical inspector of the port of St. John, died suddenly at his home in that city, Dec. 19, 1902, aged 88.

James Codrus Lawrence, M.D. Columbus (Ohio) Medical College, 1889, twice president of the Columbus Academy of Medicine, died at his home in Columbus, Dec. 23, 1902, after a long illness, from tuberculosis, aged 43.

Rush Winslow, M.D. Rush Medical College, Chicago, 1866, four times mayor of Appleton, Wis., died at St. Elizabeth's Hospital in that place, Dec. 27, 1902, nine days after an operation for appendicitis, aged 59.

William T. Hughes, M.D. University of Pennsylvania, Philadelphia, 1873, of Bedford, Pa., died at the German Hospital, Philadelphia, Dec. 21, 1902, from sepsis, following an operation for appendicitis.

William F. Penwarden, M.D. Bellevue Hospital Medical College, New York, 1883, of Grand Rapids, Mich., was instantly killed in a railway accident at Wanstead, Ont., December 26, aged 42.

George R. Weeks, M.D., surgeon U. S. V. in the Civil War, for many years a resident of Little Rock, Ark., died at his home in Los Angeles, Cal., January 1, aged 76.

George Barton Beeler, M.D. University of Maryland, Baltimore, 1876, died suddenly at his office in Baltimore, Dec. 23, 1902, aged 49.

R. Herbert Clement, M.D. Hahnemann Medical College of the Pacific, San Francisco, 1893, died in that city, Dec. 23, 1902, aged 32.

William H. Fox, M.D. University of Pennsylvania, Philadelphia, 1849, died at his home in Ashland, Va., Dec. 31, 1902, aged 80.

Deaths Abroad.

Dr. W. Bernatzik, professor of general pathology and materia medica at the Josefs Akademie at Vienna.——**Dr. W. Sobieranski,** professor of materia medica at Lemberg.——**Dr. K. v. Kupffer,** professor of anatomy at Munich, in his seventy-fourth year.——**Dr. Rudolf Massini-Meyenrock,** professor of materia medica at Basle, director of the polyclinic, and chief of the medical department of the Swiss army.

Medical Organization.

Douglas County (Kan.) Medical Society.

This society has adopted the constitution issued by the American Medical Association, and has been affiliated with the state society.

Chattanooga and Hamilton County (Tenn.) Medical Society.

The Chattanooga Medical Society met Dec. 19, 1902, and in adopting the constitution and by-laws suggested by the American Medical Association, changed its official name to the Chattanooga and Hamilton County Medical Society.

Washtenaw County (Mich.) Medical Society.

This society met at Ann Arbor, Oct. 22, 1902, for the purpose of reorganization along the lines detailed by the American Medical Association. Drs. Nathan H. Williams, Jackson, councilor for the Michigan State Medical Society, Second District; Albert E. Bulson, Jackson, president of the State Medical Society, and Victor C. Vaughan, Ann Arbor, member of the House of Delegates of the American Medical Association, spoke in favor of reorganization. The standard county constitution recommended by the Association was unanimously adopted, but certain minor changes were made to meet local conditions. Dr. Reuben Peterson was elected president; Dr. Frederick R. Waldron, vice-president, and Dr. John W. Keating, secretary-treasurer, all of Ann Arbor.

Clarksdale and Six Counties (Miss.) Medical Association.

This association was organized Dec. 10, 1902, in conformity to the plan recommended by the American Medical Association and adopted the constitution and by-laws prepared by the committee of the American Medical Association. The association includes the following six counties: Tunica, Quitman, Coahoma, Sunflower, Tallahatchie and Bolivar. The territory covered by these counties is extremely thinly settled and a society in each county was considered impracticable for scientific work. Provision, however, is made for a vice-president in each county who will represent his county in a business way, etc. The following officers were elected: President, Dr. Morris J. Alexander, Tunica; a vice-president from each county; secretary, Dr. L. D. Harrison, Clarksdale, and treasurer, Dr. James W. Gray, Jr., Clarksdale.

Societies.

Medico-Surgical Society of Camden (N.J.).—At the annual meeting of this society Dr. Paul N. Litchfield was elected president; Dr. Alexander McAllister, vice-president; Dr. Clarence B. Donges, secretary, and Dr. Joel W. Fithian, treasurer.

Fort Wayne (Ind.) Academy of Medicine.—The academy held its annual meeting, Dec. 16, 1902, and elected Dr. Charles R. Dancer, president; Dr. Robert B. McKeeman, vice-president; Dr. J. Clifford Wallace, secretary, and Dr. Adam L. Schneider, treasurer.

Fort Dodge (Iowa) Physician's Club.—This club held its first regular meeting, Dec. 9, 1902, with 16 charter members, and elected Dr. Charles J. Saunders, president; Dr. Harley G. Ristine, vice-president, and Dr. James D. Lowry, secretary and treasurer.

Weber County (Utah) Medical Society.—At its annual meeting in Ogden, Dec. 10, 1902, Dr. Amasa S. Condon was elected president; Dr. Hammond J. Powers, vice-president; Dr. George A. Dickson, treasurer, and Dr. Harry B. Forbes, secretary, all of Ogden.

Cleveland (Ohio) Academy of Medicine.—The annual election of the academy, held Dec. 19, 1902, resulted as follows: Dr. Harris G. Sherman, president; Dr. William E. Lower, vice-president; Dr. Walter H. Merriam, secretary, and Dr. Oscar T. Thomas, treasurer.

Arizona Academy of Medicine.—The regular quarterly meeting of the academy was held in Phœnix, Dec. 20, 1902, of which Dr. E. Payne Palmer was elected president; Dr. W. M. Bell, vice-president, and Dr. W. H. Seton, secretary and treasurer, all of Phœnix.

Los Angeles County (Cal.), Medical Association.—At the annual meeting, Dec. 19, 1902, Dr. Rose Talbott Bullard was elected president; Dr. Fred. C. Shurtleff, vice-president; Dr. Charles G. Stivers, secretary; Dr. Kate Wilde, assistant secretary, and Dr. John C. Ferbert, treasurer, all of Los Angeles.

Montgomery County (Ohio) Medical Society.—At its annual meeting in Dayton, Dec. 5, 1902, this society elected the following officers for the ensuing year: President, Dr. John C. Reeve, Jr., Dayton; vice-president, Dr. Charles S. Judy, Miamisburg; secretary, Dr. Wilfred J. Taylor, Dayton; treasurer, Dr. David C. Lichliter, Dayton, and censor, Dr. Francis C. Gray, Dayton.

Camden District Medical Society.—This society has adopted a resolution recommending that the New Jersey State Board of Medical Examiners refuse to recognize the certificates granted by other states, except where New Jersey's certificates are recognized. This is in retaliation to the action of some surrounding states which fail to recognize the New Jersey Board's certificates.

Dodge County (Neb.) Medical Society.—At the annual meeting and banquet of this society, held in Fremont, December 11, Dr. Robert C. McDonald, Fremont, was elected president. The other officers elected were Drs. J. S. DeVries, Fontanelle, and Frank H. Brown, Fremont, vice-presidents; Dr. Andrew P. Overgaard, Fremont, secretary, and Dr. William J. Davies, Fremont, treasurer.

Atlanta (Ga.) Medical Library Association.—Drs. William S. Elkin, Virgil O. Hardon, E. Bates Block, Floyd W. McRae, Alexander W. Stirling and Michael Hoke filed a petition in the Superior Court, Dec. 19, 1902, asking to be incorporated under the name of the Atlanta Medical Library Association, whose purpose is the formation, establishment and maintenance of a library of medicine and the allied sciences.

The Tri-State Medical Association of Western Maryland, Western Pennsylvania and West Virginia.—This association met at Cumberland, Md., Dec. 11, 1902. There was a large attendance, and papers were read by Drs. J. Wesley Bovée, Washington, D. C.; Joseph C. Bloodgood, Baltimore; Benjamin M. Cromwell, Eckhart, Md.; Asa F. Speicher, Elk Lick, Pa.; S. A. Boucher, Barton, Md.; William F. Barclay, and Xavier O. Werder, Pittsburg, and John G. Clarke, Philadelphia.

Medical and Chirurgical Faculty of Maryland—Section on Clinical Medicine and Surgery.—At the meeting of this section, Dec. 5, 1902, Dr. Julius Friedenwald showed fragments of stomach tubes, which had become broken off in the stomach of two patients, necessitating operation for their removal. He stated that he had not found cases of gastrotomy performed for such cause, in the literature. Dr. Harvey Cushing, at the

same meeting, showed a patient who had had a gunshot wound destroying the facial nerve. He had anastomosed the distal end of the facial and the spinal accessory with the result of restoring the functions of the facial.

American Congress on Tuberculosis.—A petition was filed here, Dec. 18, 1902, in the Superior Court, Atlanta, Ga., asking for a charter for the incorporation of the American Congress on Tuberculosis. The incorporators are: Dr. George Brown, Atlanta; Dr. Henry D. Holton, Vermont; Dr. Daniel Lewis, New York; Dr. J. A. Egan, Illinois; Dr. Frank Paschal, Texas; Dr. Irving A. Watson, New Hampshire, and Drs. E. J. Barrack and P. H. Bryce, Canada. The purpose of the corporation is to promote discussion and devise means of bettering the condition of persons suffering with tubercular complaints. Another object is to assist in organizinz the World's Congress on Tuberculosis.

Philadelphia Hospital Association.—Twenty-five hospitals of the city recently united in this association. Dr. J. Vaughan Merrick was elected president. The association is advisory only, and its recommendations are to be submitted to the boards of managers of the hospitals represented for their rejection or adoption. The objects of the association are: To consider questions pertaining to hospital management; to discuss matters and methods that may increase the efficiency of hospital service; to consider possible abuses and methods to protect hospitals from imposition; to confer, when necessary, with state and municipal authorities; to devise methods for protection from contagious and infectious diseases, and to secure such comity and co-operation as may promote the best interest of all the hospitals in Philadelphia and the public good.

Southern California Medical Society.—The thirtieth regular semi-annual meeting of this society was held at Pasadena and Mount Lowe, Dec. 3 and 4, 1902, with the following officers: President, Dr. Fitch C. E. Mattison, Pasadena; vice-presidents, Drs. John C. King, Banning, and F. W. Thomas, Claremont; secretary and treasurer, Dr. Frank D. Bullard, Los Angeles. At the June meeting the question of forming a society in Southern California for the prevention of the spread of tuberculosis was discussed and a committee appointed to report a plan of organization. At this meeting the report of that committee was adopted and a temporary organization effected with Dr. Francis M. Pottenger, Los Angeles, as president, and Dr. Rose Talbott Bullard, Los Angeles, as secretary. The society will be called the Southern California Anti-Tuberculosis League.

WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Twelfth Annual Meeting, held at St. Joseph, Mo., Dec. 29 and 30, 1902.

The President, Dr. James E. Moore, Minneapolis, in the Chair.

An address of welcome was delivered by Dr. J. Geiger, St. Joseph, and response was made by the president.

Evolution of the Treatment of Cancer of the Rectum.

DR. C. H. MAYO, Rochester, Minn., presented a paper on this subject. Certain definite results are desired in operations on rectal cancer, namely, permanent cure, low operative mortality and a controllable anus or its best substitute. These results are modified by location, stage of progress, and by the age and condition of the patient. Dr. Mayo gave a review of the operative treatment since 1870.

The modern surgical treatment is the block removal of the rectum, glands and gland tissue from below, in some cases, but more often by a combined abdominal and perineal method. Through an abdominal incision a low section of the sigmoid is made, this portion of the colon being saved as a fecal container, and the cut ends of the bowel inverted and closed by a circular suture, rendering the remainder of the operation aseptic. The rectum is separated laterally and below by a peritoneal incision and pushed down with the glands and fat by blunt dissection, the separation being carried as low as possible beneath the bladder, the remainder of its removal being completed through the perineum. The sigmoid is freed sufficiently to bring the cut end out of an inguinal McBurney muscle separation opening, the skin incision of which is one and one-half inches to one side, and to which the end of the sigmoid is sutured. The bowel is also sutured within the abdomen to prevent prolapse, and a pad compression of the skin-covered sigmoid loop gives a fairly controllable anus.

The main objections of the past, the author stated, are:

1. Ineffectual removal with local recurrence, so common in the perineal type.

2. The extensive mutilating character of the Kraske before operative conditions were known.

3. The frequent failure of all methods of union of proximal and distal portions of the bowel, which, when united with the destruction of the levator ani and internal sphincter, and anus saved, represented but one-third of the controlling apparatus of the bowel.

4. The frequent formation of stricture, either cicatricial or cancerous after operation, necessitating inguinal colostomy.

5. The loss of the fecal container in straightening the sigmoid.

Sentiment, and not chance, has proven the main reason for continuing to place an uncontrollable anus in an inaccessible situation. The gain in the combined operation has been in a selection of the operation to the case, radical removal *en masse*, with all glands, fat, and connective tissue, or colostomy for palliation; the retention of the sigmoid as a fecal container; the peculiar formation of the anus, giving a fair control in an accessible situation.

Carcinoma Uteri.

DR. H. C. CROWELL, Kansas City, Mo., read this paper.

Unless very early discovered, he believes that nothing is gained by hysterectomy for carcinoma of the cervix. Later operations may avail in carcinoma of the body of the uterus. The diagnosis should be confirmed by the microscope in the hands of a competent pathologist. The uterus must be freely movable, capable of being dragged down to the vulva. If not, it is probable that the disease has involved the utero-sacral ligaments and adjacent tissue, making an operation of doubtful utility. If the disease is clearly made out by touch, appearance, and clinical history, it is rarely possible to secure a radical cure by hysterectomy, if the fatal termination is not accelerated. In cases well advanced, his individual experience leads him to believe that more days or months, as the case may be, are added to the life of the patient than by any attempt at extirpation, by cutting and scraping away the necrotic tissue down to solid tissue, burning that surface with the thermocautery, and treating subsequently by touching the surface occasionally with 4 per cent. formalin. By this treatment disintegration is retarded, hemorrhage and discharges are checked, enabling the patient to recuperate sometimes to a remarkable degree. The suffering is lessened, and the patient is relieved of the shock and dangers attending more radical procedures. The essayist urged more frequent early examinations of parous women, who should be advised of the expediency of such examinations as a routine safeguard after the age of 36.

Discussion on Papers of Drs. Mayo and Crowell.

DR. M. L. HARRIS, Chicago, pointed out the necessity of making a laparotomy previous to the operation for rectal cancer if the disease extends high, and the surgeon is not perfectly sure that it is limited to the lower part of the bowel. This preliminary laparotomy should be for three purposes: (1) for examination, in order to determine whether or not the case is operable; (2) to facilitate operation, provided one is necessary; (3) to perform a colostomy if the case is inoperable. He thinks colostomy is an extremely valuable operative procedure in many cases.

DR. HENRY T. BYFORD, Chicago, thinks Dr. Crowell too pessimistic and narrated the case of a woman on whom he operated more than ten years ago, in which cancer had involved the entire cervix. The woman has not had a recurrence. He could report a number more that had recovered following operation.

DR. H. D. NILES, Salt Lake City, said that he recently had a case in which he was in doubt as to whether the stricture of the bowel was syphilitic or malignant. He used such measures as were available, and was still in doubt. He thinks in such a case it would be wise to do a colostomy, and at the same time explore parts of the bowel. An excellent result was obtained so far as the sphincter was concerned. The patient had excellent control of the bowels.

DR. A. C. BERNAYS, St. Louis, saw Dr. Mayo perform the operation described. It was a beautiful piece of surgery, and anyone who has seen this operation done will hereafter perform it in preference to any other.

DR. D. S. FAIRCHILD, Clinton, Iowa, is convinced that surgeons, after witnessing this method of operating, will conclude that it is the procedure which will be adopted hereafter.

Disarticulation of the Hip for Sarcoma of the Femur.

DR. A. E. HALSTEAD, Chicago, reported a case and remarked on the diagnosis and prognosis in sarcoma of the femur.

DISCUSSION.

DR. B. B. DAVIS, Omaha, called attention to elevation of temperature in these cases. Several years ago he had a case and his first diagnosis was osteomyelitis of chronic form rather than sarcoma, simply because of the temperature at the time, but he soon found out his mistake. In standard text-books he found no mention of elevation of temperature. This is a symptom to remember.

DR. JOHN P. LORD, Omaha, mentioned a case of carcinoma of the femoral neck following a fracture at that point from slight violence. While in flesby individuals he thinks it would be impossible to differentiate this condition by ordinary manipulative methods, yet with the *x*-rays, in fractures from comparatively slight violence, the surgeon might suspect the condition and have an *x*-ray examination to determine the early existence of the disease.

DR. WILLIAM JEPSON, Sioux City, Iowa, mentioned 6 cases of sarcoma of the femur, 2 of which developed at the upper end of the femur, and were not subjected to operative intervention. In 4 the disease involved the lower end of the femur, 3 were subjected to amputation at the junction of the upper with the middle third; the other one was subjected to primary hip-joint amputation; 2 of the 3 were subjected to secondary disarticulation of the femur at the hip-joint. One of these 2 died; also 1 not subjected to this operation. Out of 6 cases there are only 2 living.

Oblique Inguinal Hernia.

DR. A. E. BENJAMIN, Minneapolis, said there were too many methods and a too large percentage of relapses and pointed out some of the causes of imperfect results. An operation that is not altogether new, but worthy of consideration, is as follows: The patient is prepared by having the parts shaved the morning of the operation. In doing so, infected areas or vesicles are avoided, which may result, when the shaving is done the previous evening or before the parts have been thoroughly cleansed. The time intervening between the previous evening and morning of the operation favors a greater multiplication of microorganisms. The bowels are emptied and subsequently kept free from gas accumulation, which lessens the internal pressure. An ordinary incision for a Bassini operation is made. The aponeurosis of the external oblique is slit up to a point opposite the internal ring. The fibers of the internal oblique and transversalis muscles are divided by blunt dissection, thus opening the inguinal canal. The internal oblique and transversalis muscles are found closely connected. They are not separated, but the aponeurosis of the external oblique is carefully and thoroughly removed from the internal oblique. The lower portion is dissected down to Poupart's ligament, and the transversalis separated from the peritoneum. Such careful dissection and positive identification of structures are an important aid in securing direct apposition and firm union. It corrects all defects of Nature in this region. The cord is now raised and silkworm-gut sutures introduced, passing through the skin, Poupart's ligament, internal oblique and transversalis. The loop is made on the lower side of the transversalis. The needle, re-entering the transversalis and internal oblique, passes through the skin to the outer and lower side of the cut near the point of entrance. From three to five sutures are similarly introduced. These sutures pull the internal oblique and transversalis below the shelving edge of Poupart's ligament, and are observed to make a firm barrier against any internal force. The sutures are then tied over rolls of sterilized gauze. The spermatic cord rests on the internal oblique. The external oblique is then closed over the cord. Interrupted figure-of-eight sutures are introduced, bringing the external oblique in apposition with Poupart's ligament. This also approximates the skin, and the sutures are tied over a roll of sterilized gauze. The sutures are usually left two weeks.

Appendicitis and Other Cases.

DR. W. W. GRANT, Denver, reported a case of rupture of gall-bladder or duct from vomiting, with rupture of the appendix in the same patient, and also reported two cases of appendicitis because of the interest connected with drainage and phagocytosis. He is satisfied that he has saved some patients after peritoneal extravasation by the liberal use of gauze for drainage. In abdominal operations drainage imperils the integrity of the abdominal wall, therefore predisposes to hernia. It should consequently be dispensed with as soon as possible. But in a justifiable belief in the efficacy of hyperleucocytosis, he believes it is not wise to hastily discard surgical procedures which have stood the test of abundant experience. Dr. Grant also reported a case of acute yellow atrophy of the liver.

Chronic Pancreatitis and Pancreatic Cyst.

DR. B. B. DAVIS, Omaha, reported a case of each of these affections and discussed the etiology and diagnosis of pancreatitis. Infection is considered the determining factor in most cases, being secondary to gallstones, cholecystitis, gastritis, duodenitis and zymotic diseases, particularly typhoid fever and influenza. Probably syphilis, alcoholism and general arteriosclerosis also cause a small percentage.

Glycosuria, fatty stools and muscle fibers in the stools, which theoretically ought to be diagnostic factors, in pancreatic disease, practically have usually been found absent. If glycosuria is present, destruction of the islands of Langerhans has been found to exist. In all cases in which infection is the causative factor, prolonged drainage of the gall-bladder was recommended.

DR. M. L. HARRIS, Chicago, emphasized the frequency with which stomach troubles precede chronic pancreatitis. It is possible that some stomach affections or ulcers of the duodenum are undoubtedly instances of chronic pancreatitis, and may be the result of infection.

Gunshot Wounds of the Stomach.

DR. J. W. ANDREWS, Mankato, Minn., reported a case and stated that since surgeons of international reputation do not agree as to an immediate operation, he prefers to do an immediate operation in all cases where it is reasonably certain that the stomach has been perforated.

Fowler's Position in Abdominal Surgery.

DR. VAN BUREN KNOTT, Sioux City, Iowa, had employed this position and reported five recoveries from diffuse septic peritonitis, no two of which occurred without an intervening failure. These are the only cases of diffuse septic peritonitis that have been operated on by the author successfully. The Fowler position was maintained for 24 hours, unless some special reason for continuing it was present. He says that the head of the bed should be raised from 18 to 20 inches from the floor. He hoped that those present, who had neglected to employ the Fowler position, would be induced to do so, for he believes that it can do no harm, and in many cases will prove of much value.

Old Irreducible Dislocations of the Shoulder Joint.

DR. A. F. JONAS, Omaha, reported seven cases in his own practice. His method consists chiefly in (1) manipulation, using the forearm as a lever, rotating outward and inward, abduction and adduction, never forgetting for a moment a possible accident to the axillary vessels and nerves, and the possibility of fracturing the humerus; (2) if this plan fails, the capsule is incised, and all cicatricial tissue is extirpated. All muscular attachments that offer restraint are severed, the axillary vessels are protected with a broad, flat retractor, and the head of the bone is brought into place by means of an elevator, assisted by manipulation and traction. To avoid infecting the wound, in this last maneuver it is advisable to firmly wrap the entire arm and hand with wet sublimate towels. Dry towels are liable to slip and become displaced, making it possible for the operator's hand to become infected. If the head can not be replaced, then (3) the head of the humerus should be resected, an operation to be avoided, when possible, on account of the

resultant flail-like condition of the arm, and yet must be done (*a*) when the humeral head and neck become too extensively stripped of their attachments, experience having shown that necrosis may occur in 16 per cent. of cases; (*b*) when osseous union has occurred between the head and the ribs; (*c*) when, after a division of all restraining soft parts, the head rests against the point of the acromion process.

DR. ALEXANDER H. FERGUSON, Chicago, reported a case of end-to-end anastomosis of the popliteal artery for gunshot injury.

Repair of Pelvic Injuries.

DR. WILLIAM E. GROUND, West Superior, Wis., contributed a paper on "Natural and Logical Treatment of Injuries of the Pelvic Floor Occurring During Parturition."

His conclusions were that almost every woman during her confinement suffers injuries from which she does not recover unless she is subjected to a secondary operation for repair; that immediate suture of apparent lacerations does not restore pelvic support in the vast majority of instances; that from one to two months after labor the woman should be subjected to a thorough examination and any relaxation corrected, before it has had time to impair her health.

Election of Officers.

The following officers were elected for the ensuing year: President, Dr. Alexander H. Ferguson, Chicago; vice-presidents, Drs. C. H. Wallace, St. Joseph, and C. W. Oviatt, Oshkosh, Wis.; secretary and treasurer, Dr. George H. Simmons, Chicago; members of the executive council: Dr. James E. Moore, Minneapolis, chairman; Drs. A. F. Jonas, Omaha; O. B. Campbell, St. Joseph; C. H. Mayo, Rochester, Minn., and J. R. Hollowbush, Rock Island, Ill.

Denver was selected as the place for holding the next annual meeting, Dec. 28 and 29, 1903.

(To be continued.)

AMERICAN ROENTGEN RAY SOCIETY.

Third Annual Meeting, held in Chicago, Dec. 10 and 11, 1902.

The President, Dr. G. P. Girdwood, Montreal, Can., in the Chair.

X-Ray Physics.

DR. T. PROCTOR HALL, Chicago, opened the program with a paper on the physics of the *x*-ray, which he concluded are electrical waves of some sort. He exhibited a new flouroscope which, in his estimation, is far superior to any other.

Equal Potential Surfaces in X-Ray Field.

DR. JOHN C. PITKIN, Buffalo, considered the principles and mechanics of static machines in general and exhibited an apparatus of his invention illustrating that many air gaps in simple series are superior to one long interval. This apparatus consists of a glass rod about one foot in length and one-half inch in diameter, on which are slipped a number of plain brass band rings, which are freely movable, to form the intervening air gaps. This apparatus greatly intensifies the *x*-rays. He suggested that in order to avoid distortion of the *x*-ray image the fluoroscope screen and the photographic surface should be made to conform to the shape of these equa-potential surfaces.

Presidential Address.

The president, Dr. Girdwood, in his annual address, reviewed the origin and development of electricity from the time of the early Greeks. He also considered the discovery of the Roentgen ray, the skiagram and the fluoroscope, and exhibited photographs made nearly thirty years ago when the skiagram was still exceedingly crude. The apparatus in use at that time was described in full. The nature and origin of the *x*-ray was also discussed in full as well as the value of the *x*-ray as a means of diagnosis and treatment. In closing, he called particular attention to the proper naming of these rays after their discoverer, Roentgen. All great discoveries in electricity had been named after the man who was instrumental in their discovery, and there is no reason why an exception should be made in this instance. They should be known as the Roentgen ray and not the *x*-ray.

Systematic Records and the Routine Use of the X-Rays.

MR. W. J. WILBERT, Philadelphia, described the methods used in the hospital with which he is connected in the capacity of radiographer. He called special attention to the necessity and value of the routine use of the ray for diagnostic purposes, because in many instances a seemingly correct diagnosis is seen to be wrong when a skiagram is at hand for confirmation of the clinical diagnosis. This is especially true in unsuspected cases of fracture about or in joints which are usually classed as sprains or contusions or nerve injuries. Many cases were cited in support of this contention.

Skiagraphy as an Art.

DR. J. RUDIS-JICINSKY, Cedar Rapids, Iowa, read this paper and described what is absolutely necessary in order to procure a good skiagraph, the principal thing being expertness on the part of the radiographer. The expert finds things which are entirely invisible to the novice. The correct reading or interpretation of the shadows in a skiagram is by no means an easy task. He favors rapid exposures with a high current.

Results and Technic in Treating Epithelioma.

DR. EMIL H. GRUBBE, Chicago, in this paper, strongly objected to the indiscriminate use of the high and low tubes in tumors. The method is inexact and positively harmful. A tube with a vacuum just high enough to penetrate the tissues to be exposed should always be used. Inflammation of either the deep or surrounding superficial tissues should be avoided. Either the static machine or the induction coil may be used. When the static machine is used it is advisable to use at least two series of spark gaps between the machine and the tube. When the coil is used connection may be made to the tube without the use of a spark gap in series. The principal thing is to maintain a constant vacuum in the tube. The controlling factors in this method are the quality of the tube, distance of the tube from the parts to be treated, the time of exposure, frequency of exposure and exciting apparatus. The time of exposure depends on the intensity of the *x*-ray. Treatments should be given daily, with exposures of ten minutes, the tube being placed from four to six inches from the part, until a reaction ensues in the shape of redness, heat and itching. The treatments are then discontinued for from two to seven days, after which the patient is again exposed in the same manner as before and to the same rays. All parts not under treatment are protected by a mask of thin sheet lead. The occurrence of a dermatitis does not retard the progress of the cure; in fact, it may be taken as an indication that the treatment is beginning to be effectual. Proper general or systemic treatment should also be used in conjunction with the rays.

The author details a large number of cases so treated and tabulates the result. Good results were obtained in the majority of the cases, the result always varying with the location of the disease. The average duration of all treatments was four months. Some were symptomatically cured in as short a time as one month.

When the disease is situated in an accessible part of the body the chances of recovery are manifestly greater than when the location is inaccessible as the part can be brought more readily under the influence of the rays. The results obtained were of such a nature as could not have been obtained by any other method of treatment. The writer does not claim to have brought about an absolute cure, but only a symptomatic cure. He states rather positively, however, that in all complicated cases of superficial epithelioma, where the treatment was begun early, the results have been such as to warrant the use of the word "cured" in its fullest sense. In incurable cases the *x*-ray is as nearly a specific as any therapeutic agent in use to-day.

DISCUSSION.

DR. CLARENCE E. SKINNER, New Haven, Conn., did not agree with Dr. Grubbe that it was necessary to produce a dermatitis in order to get the best results from the use of the *x*-ray, although in the majority of the cases the production of some dermatitis hastens the cure.

This was also the opinion of several others who participated in the discussion. All favored a slight tanning or browning of the skin, but not actual burning.

DR. E. J. BROWN, Decatur, Ill., believes in producing a dermatitis, but finds that it is much easier to produce a burn and much harder to cure one on the body than on the face. He advocated giving the treatment in relays, as it hastens the cure and also permits of a control of the degree of a burn. The *x*-ray gives a better functional result and cosmetic effect than surgery.

The Roentgen Ray as a Therapeutic Force, from a Clinical Standpoint, with Illustrative Cases.

DR. J. B. MURPHY, Chicago, said that in the fracture element of surgery the *x*-ray is of enormous benefit, although it is liable to err. It is also of great assistance in the diagnosis of tubercular affections of the joints in differentiating whether the lesion is one of the bone or of the synovial membranes, thus materially facilitating the method of treatment and the subsequent result. The *x*-ray is further valuable in these cases as a therapeutic agent, producing remarkably good results, and in an incredibly short time. He also cited a number of cases of tuberculosis of the spine in which the *x*-ray was used for its therapeutic effect. A cure resulted in each case, in one after twenty-five applications, in another after twenty-one. A third was very much improved after twenty-three applications. He called attention to the difficulty of correctly diagnosing the presence of renal calculi with the *x*-ray. It is often deceptive, showing stones when they are not there, and not showing them when they are there. Repeated skiagraphs should be made, and always in two directions. Deep-seated tumors, as of the intestinal tract, were not affected in his experience. In intestinal and tubercular fistulas the sinuses close up promptly after only a few applications of the ray.

DISCUSSION.

DR. J. P. MARSH, Troy, N. Y., called attention to frequent blood examination for prognosis. He finds that if the leucocytes increase in number the outcome will be a favorable one, and *vice versa*.

DR. CLARENCE E. SKINNER, New Haven, Conn., said that there is considerable difference in the way in which these growths respond to the influence of the *x*-ray. He suggested that perhaps it might be called an idiosyncrasy.

Others who discussed the subject were: Drs. Gibson, Birmingham, Ala.; Dunham, Cincinnati; Edwards, Nashville, Tenn., and Pennington, Chicago.

DR. G. P. GIRDWOOD, Montreal, Can., contributed a paper describing cases of cancer, tuberculosis and rodent ulcer with the rays.

The Technic of Treatment of Malignant Growths.

DR. J. N. SCOTT, Kansas City, Mo., read this paper. He insists that the apparatus used should be powerful enough to excite the largest tube to its fullest capacity and permit of a complete control of the current. He believes that the results in malignant growths are better when the cases are treated every day. The ray should never be employed strong enough to produce a necrosis of the tissues. He begins with an exposure of four minutes and gradually increases to eight minutes when a reaction usually appears. The time of exposure is then diminished, followed by another gradual ascent until the period of reaction. This method is pursued until a satisfactory result is obtained. The growth should always be exposed from as many directions as possible.

The general condition of the patient should be carefully watched and all the functions, especially those of elimination, kept active. Dr. Scott is convinced that the Roentgen ray will cure a certain percentage of cases of malignant tumor and improve nearly all more or less. The *x*-ray is far superior to the knife in that the original tumor, as well as the metastatic growths, can be treated at the same time, thus preventing any further spread. It is also applicable where the knife is not. A special apparatus is described, devised by the author, for the purpose of preventing the possibility of producing a burn on other parts of the body, and also to protect the hands and eyes of the operator, which is a very important matter. The apparatus consists of a metal box which is perforated by openings through which the rays pass and through which the operator can also regulate his apparatus without exposing either himself or his patient. Since he has used this box he has no trouble whatever with burns of unaffected parts of the body.

DISCUSSION.

DR. GORDON C. BURDICK, Chicago, does not believe that the normal tissue should be protected in a case of carcinoma, except when the tumor involves any part of the face. In body tumors the tumor tissue will break down long before the healthy tissue.

DR. LESTER E. CUSTER, Dayton, Ohio, exhibited a screen of his invention, containing a central opening adjustable in size by a series of diaphragms. It is mounted like a music stand and is freely movable in every direction for use on any part of the body to protect the healthy tissue. It also protects the operator. The screen is made of block tin, but any kind of metal can be used. It may be packed in a small space and is easily and rapidly set up.

Election of Officers.

The following officers were elected for the ensuing year: President, Dr. Arthur Goodspeed, Philadelphia; vice-presidents, Drs. John B. Murphy, Chicago, and Wm. Jordan Taylor, Cincinnati, Ohio; secretary, Dr. J. B. Bullitt, Louisville, Ky.; treasurer, Dr. Weston A. Price, Cleveland, Ohio; member of the executive committee, Dr. Ralph R. Campbell, Chicago. The next place of meeting will be determined by the executive committee.

(To be continued.)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Prevention of Mammary Abscess.

Dr. Alfred C. King, in *N. Y. Med. Jour.*, states, in the prevention of mammary abscess, that the treatment should really begin during the latter months of pregnancy by manipulating and drawing out the nipples and bathing them in alcohol or borax water to harden the epithelium. Absolute cleanliness is requisite; frequent washing of the nipples with soap and water, followed by a saturated solution of boric acid, keeping gauze pads saturated with this solution wrapped around the nipples during the day and sterilized vaselin applied during the night. As an application also, the author recommends the following combination:

℞. Tannici (glycerite)	℥ii	8
Alcoholis	℥i	30
Aquæ rosæ q. s. ad	℥iii	90

M. Sig.: To be applied constantly on sterile gauze.

For the pain give opium or codein or morphin hypodermatically if the pain is unbearable, and apply lead and opium wash locally. Saline cathartics lessen the hyperemia of the breasts. Belladonna ointment applied locally often affords comfort. Ice bags are of great importance and should be employed in order to prevent pus formation. Support by bandages is necessary, employing the figure-of-eight in combination with the "straight around" bandage, making gentle compression as well as support. Bacon's method of massage may be employed by beginning in the axilla and rubbing under the clavicle, gently at first and gradually increasing the pressure. The stroking is all directed away from the breast and not toward it. The purpose is to facilitate the flow of the blood and lymph back from the breast and to accelerate the flow in the efferent vessels.

Potassium Chlorate in Habitual Abortion.

Dr. S. Remy, in *Merck's Archives*, recommends the use of potassium chlorate, given internally, in cases of habitual abortion in young women, which is not dependent on epidemic disease, on syphilis, or on lesions within the uterus. As soon as the patient is certain she is pregnant, she is given daily grains 3 (gm. .20) of potassium chlorate and the medication is con-

tinued during the entire period of gestation. The dose is decreased to grains 2½ (.15) during the last few weeks. The author succeeded in a number of cases which previously had had several miscarriages. He believes that the nascent oxygen liberated acts on the elements of the uterine mucous membrane in the process of evolution and gives them increased vitality.

Burns.

F. Tichy, according to an abstract in *N. Y. Med. Jour.*, recommends calcium hypochlorite as an antiseptic for burns. He applies a cool bandage with an antiseptic oil on the first day, which he finds causes the vesicles to form quickly, which he opens after twenty-four hours under antiseptic precautions. He then applies compresses steeped in the following solution:

℞. Calcii hypochloriti .....gr. xxxvi-lxxv 2.25-5
Aquæ destil. .....℥xxxv 1080
Dissolve, filter and add:
Camphoræ .....m. lxxv 5

M. Sig.: Apply locally.

The compresses should be renewed after twenty-four hours, but kept moist by pouring on fresh solution during that time. It is of importance to keep the compresses on as long as possible and to keep them constantly damp. Great care must be exercised in removing the old compresses not to disturb the scabs under which the wound is to heal.

Salicylic Acid for Soft Chancre.

The following is recommended by *N. Y. Med. Jour.* in the treatment of soft chancre:

℞. Acidi salicylici .....gr. xxiv 1 | 65
Tinct. benzoini 3ss 2
Petrolati .....℥i 30

M. Sig.: Apply locally night and morning.

Infantile Eczema.

A. Ravogli, in *Cin. Lancet-Clinic*, recommends the following treatment of eczema of infants: The patient should have plenty of water, and if necessary to further stimulate the kidneys 10 to 20 grains of potassium citrate may be added to the water daily. The elimination by the bowels must be given attention. For this purpose small doses of calomel, magnesium citrate, sodium phosphate, cascara or castor oil may be given. In cases of diarrhea, salol and sodium bicarbonate, two grains of each may be given three times a day. In poorly-nourished children tonics, iron and cod liver oil are of use. Arsenic is of no benefit in eczema.

In an acute eczema bran or starch water or a mild solution of sodium bicarbonate should be used for bathing instead of soap and water. The clothing should not be so excessive as to keep the child constantly in perspiration. The local treatment must be governed by the stage of the disease. Dusting powders like zinc oxid, bismuth or rice powder and boric acid should be employed in the acute form when it is of an erythematous nature located around the genitals and in the folds of the skin. In the acute form, with deep excoriations, accompanied by abundant serous discharge and severe itching, the use of ichthyol in the form of a liniment as follows is of great value:

℞. Ichthyol 3ii 8
Olei amygdalæ dulc.
Aq. calcis, āā 3iv 16
Aq. rosæ
Glycerini, āā .....℥i 30

M. Fiat linimentum. Sig.: To be applied on strips of lint saturated with the liniment. According to the author, ichthyol cornifies the epidermic cells of the corpus mucosum and forms a temporary protection to the papillary layer. The surface of the skin should be washed with a 1 per cent. solution of carbolic acid or sodium borate before the liniment is reapplied.

In cases of acute eczema the following is recommended as a sedative lotion:

℞ Pulv. calamin prep.
Zinci oxidi, āā 3ii 8
Glycerini
Aquæ rosæ, āā .....℥iss 45

M. Sig.: Apply locally to the affected surfaces with a camel's hair brush or on pieces of lint.

In order to maintain the remedies on the scalp it is necessary to cut a mask which may be fastened to a skull cap and bound to the head. Resorcin should be employed when there is a marked seborrheic condition of the scalp and face. It may be applied in the form of an ointment as follows:

℞. Resorcin .....gr. x | 65
Ung. aq. rosæ .....℥i 30

M. Sig.: Apply locally; or:

℞. Resorcin .....gr. xv 1
Acidi salicylici .....gr. vi | 20
Vaselini flavi .....℥i 30

M. Sig.: Apply locally.

The foregoing cleanses the surface, diminishes the exudation and secretion of the sebaceous matter. As a continuation of the treatment pastes such as Lassar's may be applied to protect the parts:

℞. Acidi salicylici .....gr. x | 65
Zinci oxidi 3ii 8
Amyli 3ii 8
Vaselini .....℥i 30

M. Sig.: Apply locally.

In eczema, accompanied by prurigo, sulphur mixed with the foregoing paste gives good results. In cases of pustular eczema of the scalp a salve containing white precipitate, likewise produces good results:

℞. Hydrarg. precip. albi .....gr. x | 65
Zinci oxidi
Bismuthi subcarb. 3ss 2
Acidi carbol. .....gtt. x | 65
Vaselini flavi .....℥i 30

M. Sig.: Apply locally.

When the inflammation has subsided and the epidermis is reforming and the exudation has been reduced the application of a combination containing tar is of service:

℞. Ung. picis liq. 3iii 12
Zinci oxid. 3iss 6
Ung. aq. rosæ 3vi 24

M. Sig.: Apply locally.

Where it is difficult to keep the mask and ointment on the face, the Pick paste may be applied.

℞. Zinci oxidi 3ii 8
Pulv. tragacanthæ 3i 4
Glycerini 3iss 6
Aq. rosæ .....℥iv 120

M. Sig.: Apply locally.

Carbolic acid or tar may be substituted in proper proportions for the zinc oxid. When the eczema has healed up but the skin is tender and easily cracks and itches the following should be applied:

℞. Acidi carbol. 3i 4
Glycerini 3i 4
Aq. rosæ
Alcoholis, āā 3iii 12

M. Sig.: Rub on the skin with absorbent cotton and then dry and dust with rice powder.

Capillary Bronchitis in Children.

The prognosis of capillary bronchitis is dependent to a great extent on the age and state of nutrition of the patient. In children under twenty months it is more grave and may terminate fatally within twenty-four or thirty-six hours. To control the temperature tepid sponging or bathing should be resorted to. Warm mustard baths serve two purposes in this disease: first, to reduce the temperature, and secondly, to modify the state of congestion of the pulmonary circuit by dilating the peripheral capillary vessels. The strength of the mustard bath should be one tablespoonful of mustard to the gallon of water. The bath may be repeated every three or four hours if necessary. It has been recommended to put one tablespoonful of mustard in a quart or half gallon of water and, wringing a towel from this solution, wrap the infant in the towel and allow it to remain there for ten or twenty minutes, when the skin will become reddened. Mustard paste applied to the anterior portions of the chest or posteriorly over the base of the lungs is of undoubted value in relieving the congestion and lessening the

difficulty of respiration to some extent. The paste should be made up from one part of mustard to six of flour, and in older infants a comparatively stronger paste may be used. The elimination, respirations and heart's action must be carefully watched and the presence or absence of cyanosis observed. There is, however, great danger in over-stimulation in these cases in the anxiety to relieve the dyspnea.

Small doses of spirits of nitrous ether repeated four or five times in the twenty-four hours are of service in increasing the renal elimination. To support the respirations small doses of spiritus frumenti or strychnin may be employed, depending on the rapidity of the respirations and the heart's action. For a child of fifteen or twenty months the dose of strychnia should range from gr. 1/300 (.0002) to gr. 1/200 (.0003), given every four hours.

In order to render the mucous secretion in the capillary bronchi less viscid and thus aid the little patient to clear the finer air-passages and at the same time to lower the temperature by increasing elimination, the following combination may be given:

℞.	Ammon. carb. .....gr. viiss-xv		50-1.
	Liq. ammon, acetatis .....ʒi	30	
	Aq. destil. q. s. .....ʒii	60	

M. Sig.: One teaspoonful every four hours, alternating with the strychnia.

An emetic is sometimes given to advantage when the infant is unable to raise the mucus.

Small doses of calomel should be given in divided doses at the beginning of the attack.

Medicolegal.

County Physician Refusing to Act in Epidemic—Expense.—The Minnesota statutes provide that, on the breaking out of epidemics of contagious and infectious diseases, the constituted authorities, who are present and have notices thereof, have power to act, and that all necessary expense incurred by any board of health in the general control of contagious and infectious diseases within any town, village, or city shall be a charge in favor of such town, village, or city against the county in which the same is situated. The Supreme Court of Minnesota holds, in the case of the City of Mankato vs. Blue Earth County, that the health officer of a municipality is justified in incurring the expense of furnishing medical treatment for the purpose of controlling a contagious disease, when the county physician, whose duty it is, refuses to treat the infected persons, and such expense may be recovered against the county. It says that it was suggested in this case that it was not in the power of the county physician to refuse; that he should have been compelled to perform his duty, or, if he would not, then application should have been made to the county commissioners to secure the requisite services. But the court does not think that the statute justifies such construction. It says that it is the evident intent and spirit of the whole law to provide a speedy method of controlling and stamping out such diseases, and, although it was made the duty of the county physician to perform such services, it would be unreasonable to require the public to undergo the delay and suspense attendant on securing another representative of the county in the manner suggested. It must be assumed that, for the purpose of caring for people afflicted in such a manner, the county physician is the duly accredited representative of the county, and a refusal on his part to perform the services was ample justification for the health board to take the matter in their own hands, and furnish the medical attendance necessary to control and eliminate the infection. No distinction can be drawn between expenses incurred in removing the patients into quarantine, furnishing them shelter and necessary supplies for their comfort, and the expense of medical attendance, for such services are required not only to allay the sufferings of patients, but also to control the epidemic. Furthermore, the county is liable, the court holds, for the necessary additional salary paid the local health inspector for extra services in locating and combating contagious diseases.

Mental Healing Under the Postal Laws on Fraud.—The case of the American School of Magnetic Healing and another vs. McAnnulty, to enjoin the latter, as postmaster at Nevada, Mo., from carrying out a fraud order of the postmaster-general to withhold their mail, was tried on demurrer, that is, admitting all material facts in the bill of complaint, and denying that under them the complainants were entitled to any relief. It was therefore admitted that the business of the complainants was founded "almost exclusively on the physical and practical proposition that the mind of the human race is largely responsible for its ills, and is a perceptible factor in the treating, curing, benefiting, and remedying thereof, and that the human race does possess the innate power, through proper exercise of the faculty of the brain and mind, to largely control and remedy the ills that humanity is heir to, and complainants discard and eliminate from their treatment what is commonly known as divine healing and Christian science, and they are confined to practical scientific treatment, emanating from the source aforesaid." Can such a business be properly pronounced a fraud within the statutes of the United States? The Supreme Court of the United States answers that there can be no doubt that the influence of the mind upon the physical condition of the body is very powerful, and that a hopeful mental state goes far, in many cases, not only to alleviate, but even to aid very largely in the cure of an illness from which the body may suffer. And it is said that Nature may itself, frequently, if not generally, heal the ills of the body without recourse to medicine, and that it can not be doubted that in numerous cases Nature, when left to itself, does succeed in curing many bodily ills. How far these claims are borne out by actual experience may be matter of opinion. Just exactly to what extent the mental condition affects the body, no one can accurately and definitely say. One person may believe it of far greater efficacy than another, but surely it can not be said that it is a fraud for one person to contend that the mind has an effect on the body and its physical condition greater than even a vast majority of intelligent people might be willing to admit or believe. Even intelligent people may and indeed do differ among themselves as to the extent of this mental effect. Because the complainants might or did claim to be able to effect cures by reason of working on and affecting the mental powers of the individual, and directing them towards the accomplishment of a cure of the disease under which he might be suffering, who can say that it is a fraud, or a false pretense or promise within the meaning of these statutes? How can any one lay down the limit and say beyond that there are fraud and false pretenses? The claim of the ability to cure may be vastly greater than most men would be ready to admit, and yet those who might deny the existence or virtue of the remedy would only differ in opinion from those who assert it. There is no exact standard of absolute truth by which to prove the assertion false and a fraud. We mean by that to say that the claim of complainants can not be the subject of proof as of an ordinary fact; it can not be proved as a fact to be a fraud, or false pretense or promise, nor can it properly be said that those who assume to heal bodily ills or infirmities by a resort to this method of cure are guilty of obtaining money under false pretenses, such as are intended in the statutes, which evidently do not assume to deal with mere matters of opinion on subjects which are not capable of proof as to their falsity. We may not believe in the efficacy of the treatment to the extent claimed by complainants, and we may have no sympathy with them in such claims, and yet their effectiveness is but matter of opinion in any court. The bill in this case avers that those who have business with complainants are satisfied with their method of treatment, and are entirely willing that the money they sent should be delivered to the complainants. In other words, they seem to have faith in the efficacy of the complainants' treatment, and in their ability to heal as claimed by them. If they fail, the answer might be that all human means of treatment are also liable to fail, and will necessarily fail when the appointed time arrives. There is no claim that the treatment by the complainants will always succeed. To further illustrate what it means, the Supreme Court refers to the difference of opinion as to the value of electricity in treating disease, of

vaccination as a preventive of smallpox, and of homeopathic treatment. Both the homeopathic and what is called the "old school," it says, have their followers, and many who believe in the one will pronounce the other wholly devoid of merit. But there is no precise standard by which to measure the claims of either, for people do recover who are treated according to the one or the other school. And so, it is said, do people recover who are treated under this mental theory. By reason of it? That can not be averred as a matter of fact. Many think they do. Others are of the contrary opinion. Is the postmaster-general to decide the question under these statutes? The court holds not. As the effectiveness of almost any particular method of treatment of disease is, to a more or less extent, a fruitful source of difference of opinion, even though the great majority may be of one way of thinking, the efficacy of any special method, it declares, is certainly not a matter for the decision of the postmaster-general, within these statutes relative to fraud. Unless the question may be reduced to one of fact, as distinguished from mere opinion, these statutes can not be invoked for the purpose of stopping the delivery of mail matter. And in this case, it simply holds that the admitted facts showed no violation of these statutes. Its instructions to overrule the demurrer are coupled with others that it be with leave to answer, and to take such further proceedings as may be proper and not inconsistent with this opinion. In overruling the demurrer, it adds, it does not mean to preclude the postmaster from showing on the trial, if he can, that the business of the complainants, as in fact conducted, amounts to a violation of the statutes as herein construed.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

December 27, 1902.

1 *The Diagnosis of Cancer of the Stomach. William F. Cheney.
2 *Lumbar Puncture as a Curative Agent in Meningitis, with Report of a Case. S. Ormond Goldan.
3 *An Autopsy Four Hours Postpartum on a Subject on Whom Ventral Hysteropexy Had Been Done Four Years Previously. Byron Robinson.
4 *Hydrops Tubæ Profluens, with Report of Cases. F. Hurst Maier.
5 A Case of Corrosive Sublimate Poisoning from a Vaginal Douche. Horatio C. Wood, Jr.
6 A Case of Herpes Zoster Ophthalmicus Complicated by Oculomotor Palsy. William Zentmayer.

1. **Cancer of the Stomach.**—Cheney notes the symptoms of gastric cancer, and says that where there is no tumor the difficulty may be much greater and the diagnosis of Bright's disease and pernicious anemia may require careful study, but it is in these cases that cure by operation is the most possible.

2. **Lumbar Puncture.**—Goldan reports a case of meningitis in a child, accompanied with convulsions and marked swelling of the fontanelle. Lumbar puncture was made with the idea of relieving the pressure and with strikingly good immediate results. He thinks that lumbar puncture with aseptic precautions is devoid of any risk, and while valuable from a diagnostic point of view, may be also curative in certain cases.

3. **Ventral Hysteropexy.**—In the case reported by Robinson death was caused by invagination of the postpartum uterus, due to ventral hysteropexy performed four years previous. The direct cause was atrophy of the fundus due to dragging of the peritoneal band on the fundus. The direct cause of death was heart shock, which he explains by the effect of trauma on the heart through the hypogastric and ovarian plexuses, solar plexus, and splanchnics to the cervical ganglia. He concludes that ventral hysteropexy should not be performed on women in the reproductive period.

4. **Hydrops Tubae Profluens.**—Two cases are reported by Maier, who remarks that the pathology is the same as that of ordinary hydrosalpinx, differing only in the fact that the occlusion is mechanical and finally gives way to pressure. He notices the theory of Menge and Döderlein that it is due to mild streptococcic infection of puerperal origin and with the possibility also of gonorrheal infection.

Medical Record, New York.

December 27, 1902.

7 *On Some of My Principles in Orthopedic Surgery. Adolf Lorenz.
8 *What Can Be Done to Prevent the Spread of Syphilis. E. Harrison Griffin.
9 *X-Light in Therapeutics. Clarence E. Skinner.
10 *Typhoid Gangrene. Charles E. Nammack.
11 *The Etiology of Relapse in Typhoid Fever. H. N. Rafferty.
12 *Pasteurized and Sterilized Milk as a Cause of Rickets and Scurvy. E. M. Sill.

7. **Orthopedic Surgery.**—Lorenz gives the following principles as guiding him in his operations: 1. Avoidance of even the possibility of putting the life of the patient in danger. For this reason he generally prefers the bloodless operations, and osteoclasis to osteotomy. 2. The so-called central correction of deformities, which means that every deformity should be corrected in the vertex of its angle. If one prefers to correct the deformity in one of the sides of the angle, the deformity itself would remain, and instead of correction we would have only a compensation. 3. Another important principle is that of absolutely saving the bones by dividing the soft parts as far as circumstances may demand it. This condemns all cuneiform osteotomies and resections *en bloc* of bone, and substitutes for them simple linear osteotomy. 4. In tuberculous disease of the joint in children, he rather favors expectant treatment. He has never made a resection of a tuberculous joint; the results of conservative treatment seem to him far the best. In hip-joint disease he aims to procure a solid ankylosis; experience has taught him that great mobility and bad function with lack of endurance are common allies. He makes little of permanent extension, and considers it only a matter of fixation, proclaiming that every articulation attacked by chronic disease should not be prevented from function any longer than absolutely necessary.

8. **Syphilis.**—Griffin notices the causes which he has observed, and, aside from the sexual causes, he mentions drinking fountains, and suggests that public drinking fountains be supplied with a cone-shaped cup without a base, which should be kept inverted over the water jet and thus constantly rinsed. He notices also the common prevalence of buccal syphilis, and the habit that the victims have of picking the sores on their mouths and leaving the virus on whatever they handle, doorknobs, glasses, etc. Laundresses are liable to acquire the disease, and he notices especially cases among nurses, midwives, etc. He thinks syphilis should be a notifiable disease, and the victims placed under surveyance. He lays down certain hygienic rules, including all the precautions against the spread of the disease, the prohibition of alcoholic drinks and of marriage for three years.

9. **The X-Light.**—From an analysis of published cases and from his own observations, Skinner concludes: 1. That the pain in deep-seated cancer is removable by the *x*-light to an extent ranging from slight amelioration to entire disappearance in a large proportion of cases, whereby the patient is enabled to spend what remnant of life is left him in comfort and free from the effects of the continuous use of opium. 2. In many cases the *x*-light is capable of exercising an influence on deep-seated cancer of sufficient intensity to markedly retard the progress, prolonging life where it can not be ultimately preserved. 3. In a proportion of cases it possesses the power to entirely overcome deep-seated malignant processes, restoring the patient to apparent health. 4. A small number of deep-seated malignant growths seem insusceptible to the *x*-light. 5. The phenomena consisting of chills, rise of temperature, etc., indicating systemic toxemia, not infrequently accompany the development or liberation of a toxin probably dependent on retrogressive metamorphosis occurring in the tissues which have become too deeply involved to be susceptible to regeneration. This auto-infection is capable of overwhelming the patient, hence it is desirable to suspend treatment temporarily when this systemic toxin first appears, and allow the system to rid itself of the noxious accumulation before further use of the rays. He believes his experience, in connection with the uniformly gratifying results met by nearly everyone in superficial growths, leads to the conclusions: 1. That a greater pro-

portion of cures can be obtained by this than any other method, possibly excepting the mercuric cataphoresis of Massey. 2. That in all cases of cancer where it is advisable to use the knife, the influence of the *x*-light in antagonizing cancerous degeneration may be looked on as indicating its application for a time immediately succeeding the operation in all cases and also in some cases preceding it. 3. That the *x*-ray is indicated in all inoperable cases because it has been successful in some and improved others, and, 4, lastly, it is the only measure that offers anything whatever of hope for ultimate recovery. He remarks on the possibility of *x*-ray lesions and the methods of producing the rays. He prefers the static machine exclusively for internal cancers, and the coil or static machine indifferently for superficial ones. Therapeutic applications of the *x*-ray should be entrusted, he thinks, only to the experienced operator, as the difference between efficient and faulty technic will determine the success or failure.

10. **Typhoid Gangrene.**—This condition, due to obstruction of the circulation from altered blood, weakened heart and mechanical embarrassments and local diffusion of bacteria, is observed in four different forms: 1, arterial thrombosis of cardiac origin; 2, autochthonous thrombi in the arteries; 3, autochthonous thrombi in the veins, and 4, thrombi in the small peripheral vessels. In the case here reported the gangrene affected both the lower extremities simultaneously, and the diagnosis was arterial thrombi of atheromatous origin, involving the aorta at its bifurcation.

11. **Typhoid Fever.**—The object of Rafferty's article is to point out the possibility of a large percentage of relapses in typhoid being due to gall bladder and liver colonization by the germs, subsequently reinfecting the duodenum and lower bowel by the bacilli-laden bile. He reports a case illustrating these views, and quotes authorities and gives references.

12. **Infantile Scurvy.**—Sill has observed 179 consecutive cases of infants fed with pasteurized and sterilized milk, and found in 97 per cent. of them unmistakable signs of rickets and scurvy, least marked in those cases where the feeding was supplemented with a small proportion of breast feeding. He thinks cow's milk is not bettered by sterilization or pasteurization for children. The better plan would be to thoroughly study the source and be able to exclude the possibility of disease. Sterilized or pasteurized milk, he says, is to the infant what canned or salt food is to the sailor.

Medical News, New York.

13 *Recent Advances in Electrotherapeutics. William J. Morton.
14 Imitation, Suggestion and Social Excitements. John B. Huber.
15 *Cutaneous Angiomata and Their Significance in the Diagnosis of Malignant Disease: A Statistical Study Based on the Observation of Nearly 400 Cases. Douglas Symmers.
16 *The Rapid Microscopical Diagnosis of Fresh Tissue; with Special Reference to Staining. F. T. Billings.
17 *Indications for the Performance of the Mastoid Operation. William C. Braislin.

13. **Electrotherapeutics.**—Aside from the older methods of franklinization which still have their value, Morton includes among the recent advances in electrotherapeutics: 1. The static induced current; 2, the wave current (a phase of the static induced); 3, the Tesla transformer of the static induced; 4, the D'Arsonval transformer of the static induced; 5, the Oudin resonator. The first, the static induced, is local and direct in its application, and reaches a far greater extent of tissue, owing to its potential and consequently diffuse power, than the galvanic and faradic currents. The second is almost entirely general, but may be either local or general, and the same applies to the transformed currents of Tesla and D'Arsonval. The Oudin resonator enormously increases the difference of potential of high frequency currents, and in itself creates a new field of application of high tension electricity, especially in local treatments and reactions. He mentions the methods of administering these currents, the use of the brush discharge, etc., and the vacuum or Geissler tube, also the remarkable effects of actinic rays.

15. **Cutaneous Angiomata.**—Symmers has investigated some 373 cases for angiomata and finds them increasingly present up to an advanced age, the percentage being greatest between 70 and 80 years, his results in this respect agreeing closely with the statistics of Raff. He has also studies 17 cancer cases which were available, in which there was no question in the diagnosis as to their relationship with angiomata. He found angiomata present in 13 cases, absent in 4, but in no case were they present in noticeably large numbers nor did they seem to bear any special relationship to cancer. He discusses the literature and concludes that skin angiomata bear no relationship to malignant disease, and that their existence, even in large numbers, is to be viewed without any degree of alarm so far as cancer is concerned. They are a frequent, practically an invariable, concomitant of decay of advanced years, and in both young and old are probably significant of some form of well-marked arterial degeneration. He remarks in a note that Rosenbaum has recently published a series of 400 observations, the results of which and the author's conclusions are essentially identical with those given in this paper.

16. **Fresh Tissue Section.**—Billings describes the methods employed for cutting and preparing fresh tissue sections. He finds hematein the best stain for nuclei, which is usually used in the form of hemalaun after P. Meyer's formula modified by Pick. It is prepared as follows: (*a*) Hematein, 1 gm., alcohol 90 per cent., 50 c.c.; heated over water bath. (*b*) Powdered alum, 50 gms., water, distilled, 1000 c.c.; heated over water bath, alum dissolved. The two solutions are poured together and allowed to cool. This is best after standing for some time; Pick leaves it untouched for six months. The different steps of hardening and staining are given as follows: 1, fresh specimen set on freezing stage, frozen and cut; 2, sections wiped off knife and placed in water; 3, alcohol, 50 per cent., two minutes; 4, alcohol, 95 per cent., three minutes; 5, hemalaun, three minutes; 6, wash in water; 7, alcoholic solution of eosin, 30 seconds; 8, alcohol, 80 per cent., three minutes; 10, carboxylol, two or three minutes; 11, mount in Canada balsam. The whole process, cutting included, should not take over twenty-five minutes. The result, as a rule, is entirely satisfactory. The results are certainly as good for all practical purposes as the prolonged hardening and embedding in paraffin or collodion, which are difficult and expensive.

17. **The Mastoid Operation.**—Braislin says the symptoms of greatest significance in leading one to undertake immediate operation are:

1. Pain continuous and severe, making sleep impossible, and radiating upward along the side of the head to the vertex, backward to the occiput, or more rarely, forward to the frontal region. 2. The temperature, even in children, does not often keep at a high point after the first days of acute illness, but is often markedly irregular. 3. A falling of the posterior superior wall of the external auditory canal. This is caused by edema of the periosteum and tissues over the mastoid cells or may be due to the actual burrowing of pus. It is possible to mistake this condition for furuncle of the canal and *vice versa*. 4. Tenderness over the mastoid is the rule in cases calling for operation, but there are exceptions. Other severe symptoms may be present pointing to perforation of the tegmen tympani.

Some operators go to the extreme of believing that an exploratory mastoidectomy is justifiable at any time, but Braislin thinks that many of these cases would recover without operation and conservatism would be preferred by most of us as applied to our own mastoids. He thinks it is proper to operate on cases in the quiescent chronic state to prevent destructive processes and further serious consequences. Stacke's operation can often be done in this condition with benefit, and with a shorter convalescence, but the lack of pain or serious subjective symptoms often prevents permission to operate.

19 Retrocecal Abscess Developing Three Years After Removal of the Appendix. Thomas S. Cullen.
20 *Personal Experience with McGraw's Method of Gastroenterostomy. Samuel Lloyd.

18. **Deformed Fractures.**—Beck's paper is fully illustrated with skiagrams showing the deformities that may exist after fractures, and illustrating his methods of their repair. He remarks that until the Roentgen rays made the diagnosis of

these deformities possible and the outlining of operative measures, indifference in regard to these cases was more justifiable. He also remarks on the necessity of fixation and the occasional advantage of wiring, though he avoids this whenever possible. If it is done he leaves the ends out, enclosed in iodoform gauze. Screws, clamps, etc., should only be resorted to under extreme conditions. The fragments of the bone in their normal position may require more or less extensive chiseling or sometimes excision of the parts of the bone. Involvement of the nerves may be suspected whenever there is intense pain or numbness in the range of their course. In fractures of the lower half of the humerus or the upper end of the fibula, the possibility of nerve interposition should never be lost sight of. The *x*-rays give us no information as to this particular point. He remarks that, of course, such deformities as are here represented should not occur at all, and it would be a most desirable thing if they were always due to the patient's own neglect and disobeying of orders.

21 *Influenza and the Nervous System. Smith E. Jelliffe.
22 *A Case of Acute Intestinal Obstruction Caused by a Gallstone: Necrosis of the Bowel; Operation; Death. J. A. Scott.
23 *The Surgical Treatment of the Enlarged Prostate. George E. Armstrong.
24 *Sore Throat. B. F. Randolph Clark.
25 *Neurasthenia. T. W. Keown.

21. **Influenza and the Nervous System.**—The history of the present epidemic of influenza in its effects on the prevalence of nervous disease, insanity, etc., is noticed by Jelliffe. He quotes from various authorities as to the increase of psychic disorders, especially the exhaustive types, and calls attention to the affinities with neurasthenia. The popular diagnosis of influenza is often erroneous. The clinical symptoms may be similar in the ordinary colds and conditions which have an entirely different bacteriology, and the necessity of bacteriologic examination and diagnosis is mentioned. The increase of suicide within the influenzal decade of 1890 to 1900 is also particularly remarked on. In conclusion he says that although the mortality of influenza and its collateral affections falls short of that recorded in the great epidemic, the situation is still a serious one, and he advises as to prophylactic measures. It is not advisable to visit persons sick with influenzal disease, but if it is necessary it is best to avoid any unnecessary contact and use disinfectants, washes, etc., and the airing of garments and exposure to the direct rays of the sun afterward. Those who are exposed to the infection should watch their general health and avoid any indulgence in alcohol. With the initial symptoms, the patient should go to bed and call for a physician. The complications are too serious to allow of risk. After the disease has passed, all articles used in the sickroom should be disinfected. These, he says, may seem to be unnecessary precautions, but the disease is so infectious and its consequences so far reaching that it is wise to take the risk seriously.

22. **Gallstones.**—The title of Scott's article gives the main facts. He concludes it with a general discussion of obstruction of the bowels, with special reference to the possibility of gallstone complications.

23. **Surgery of the Prostate.**—Armstrong formerly used the operation of suprapubic prostatectomy, but not with very successful results, and therefore gave it up, nor did he have much better success with Dittel's perineal operation when he employed that. It then occurred to him that in view of the favorable statistics of Bottini's method, that still better results would follow a more thorough and systematic use of the cautery and that through a suprapubic cystotomy wound the prostate could be thoroughly exposed and the cautery applied directly to the point where it could do the most good. He put this idea into practice in the spring of 1900, and reports seven cases. He claims for the method a great degree of safety; the cautery applied directly to the prostate, the parts and instrument being in full view, is a safe operation and can be recommended with confidence. The operator can recognize just how far the prostate extends into the bladder and which lobes require treatment, and demonstrate the condition of the bladder wall and remove any stone that is present. As much tissue as is desired can be removed and a cicatrix is left which, in healing, undergoes the inevitable contraction and opens and lowers the internal orifice of the urethra and tends to raise the floor of the bladder. Hemorrhage can be effectually controlled. Up to the present he has endeavored to close the bladder after operation, but his experience has led him to the plan of leaving it closed excepting for a drainage tube, which can be removed after the charred tissue has passed away, and any possible obstruction of the urethral orifice is out of the question. The bladder wound will close very quickly after the tube is removed. He notices in conclusion Bouffleur's article in the *Annals of Surgery* for July, where he recommends a very similar operation. He would go further than Bouffleur, however, and remove all the projecting parts of the prostate.

24. **Sore Throat.**—Clark's paper is a review of the different forms of sore throat, anginas, ulcerations, abscesses, tonsillitis, catarrhal pharyngitis, mycosis, quinsy, syphilitic sore throat, traumatic conditions, etc. The pain attending laryngeal troubles is usually described as sore throat. The treatment of the different forms is described.

25. **Neurasthenia.**—This is a general discussion of the subject. Keown calls attention to gastric disturbances as having much to do with the condition in some cases through autointoxication, and he is inclined to credit the sympathetic system as the principal nerve apparatus concerned in this disease. It is an irregular vasomotor control, which he thinks has much to do with the production of the symptoms.

28 *Obstetrical Antisepsis. Warren R. Gilman.
29 *Errors in the Estimation of Urea by the Hypobromite Method. Elliott P. Joslin.

26. **The Teaching of Physical Diagnosis.**—Thayer's article is a full exposition of his ideas in regard to this department of medical teaching, and he emphasizes the following points: 1. An essential part of the teaching of physical diagnosis consists in the demonstration of those points in regional anatomy, an accurate knowledge of which is necessary to the diagnostician. Such demonstration should be accompanied by exercises in the application of the fundamental methods of physical examination to the normal individual. 2. The student should learn, so far as possible, by actual observation and practice, the physical causes for the signs to be noted on inspection and palpation and elicited by auscultation and percussion of the normal subject; without this a proper understanding of the pathologic signs and deviations is impossible. 3. A thorough training in pathologic anatomy is essential and frequent demonstrations in the necropsy room of the lesions which the student is meeting in the living individual form an important part of the course. 4. The study of physical diagnosis should be approached without preconceived ideas beyond those acquired in the normal individual, and books should not be allowed to be consulted until the student has learned to detect in the living subject the more important manifestations if disease. Acquiring first ideas from text-books is apt to produce bad habits which may affect his diagnostic abilities later. 5. To thus properly train the student requires that the class be divided into small sections, so that each man may personally test each observation. 6. As a part of the course the student should have a fair experience in the examination of patients as they come to the out-patient clinic in order that he may acquire the skill in taking histories, in the practice of topographic percussion, and in the habit of forming an independent diagnosis. This should be under the direct supervision of the instructor. 7. No man is properly fitted to begin the practice of medicine who has not had a reasonable amount of actual bedside experience of the more important diseases he has to meet. This can be done by: 1, insisting that the student shall have several months' experience as a clinical clerk in the hospital wards; 2, by providing for daily or frequently repeated ward visits with an instructor for at least an equal length of time. This is in no way detrimental

to the interests of the patients or the institution. A great deal, of course, depends on the instructor. The teacher must be enthusiastic and absorbed in his subject, and be able to communicate these qualities to his students.

27. **Landry's Paralysis.**—After reporting two cases in which the postmortem revealed nothing adequate to account for the symptoms, Taylor and Waterman discuss the propriety of the name "Landry's paralysis," which they think is perhaps still justifiable for such cases where after adequate study no anatomic changes are found postmortem.

28. **Obstetric Antisepsis.**—Gilman's article is a full and detailed general review of the antiseptic measures that should be employed in obstetric practice.

29. **Urea Estimation.**—Joslin points out that the hypobromite method for estimating urea is not safe clinically when ammonia, acetone and *b*-oxybutyric acid and ammonia are present in the urine. Other bodies like creatinin, uric acid and urates also interfere with the test, but to a less extent. Since acetone, *b*-oxybutyric acid and ammonia are chiefly found in diabetic patients, it is a good rule to scrutinize carefully reports of large quantities of urea in this disease, since if these are present, the estimation is untrustworthy if the hypobromite method is employed. The simplest method to enable us to judge of the presence of these substances is the ferric chlorid test for diacetic acid and when this is positive, acetone and *b*-oxybutyric acid are always present, and an excess of ammonia is probable.

32 *A Contribution to the Study of Herpes Progenitalis. Noah E. Aronstam.
33 *The Hydrotherapeutic Treatment of Typhoid Fever. Henry B. Favill.

32. **Herpes Progenitalis.**—This condition is described by Aronstam, who attributes it to a peripheral neuritis or local vasomotor paralysis as its chief underlying pathologic state. He notes also its occurrence in the later secondary stage of syphilis, but is not prepared to say in what relation the two disorders stand to each other. It may also, according to reports, be associated with tuberculosis, and various local conditions may also be causal factors. The indications of treatment are to remove the cause and treat any existing systemic disorder; observe strict cleanliness of the parts; use protectives to exclude any irritation or infection of the lesions. If the latter has occurred in spite of all efforts against it, treat the resulting ulcer antiseptically. He advises for protective applications, powders of bismuth and boric acid with aristol, or zinc oxid and bismuth with europhen, first applying a little glycerin to ensure their adhesion.

33. **Typhoid Fever.**—Favill describes the bath treatment of typhoid, using the bed bath. The patient can be kept in the tub for varying periods. It looks, he says, like maltreatment, the patient shivers, complains, and looks blue, but when once taken out and rolled in blankets he immediately goes to sleep, and sometimes continues sleeping for hours. This kind of a bath can be given in any house where there is a person who can devote his attention to the patient. The reduction of temperature is not the special point and sponging and packing are not adequate substitutes.

40 A Plea for the More Frequent Use of Accouchement Force. Christopher Tompkins.

34. **Albuminuria.**—A number of cases of transient albuminuria are reported by Gordon, in all of which the morbid product disappeared under proper treatment, and they illustrate what may be variously termed physiologic, cyclic, intermittent, periodic, and functional albuminuria. He discusses them and says that if transient albuminuria is not to be regarded as a normal occurrence, it should be considered simply as an indication of disordered health due to temporary crippling of the physiologic processes of the body. He is inclined to think that many of the cases are indications of uric acidemia or some gastrointestinal disorder.

35. **Diphtheria Antitoxin.**—Holladay reports the case of a young man aged 26 years who took a prophylactic dose of 500 units and went into a condition of profound cardiac depression and syncope. He was revived with nitroglycerin, strychnin and digitalis, followed by mustard poultices, together with the continuance of nitroglycerin, and it was half an hour before any pulsation could be felt in the radial arteries. A sensation of painful constriction of the chest-impeding respiration was present for a much longer time. Holladay had used an equal quantity on himself without ill effects, and he thinks the occurrence points to an idiosyncrasy to antitoxin in this case and suggests caution in the use of this powerful prophylactic and curative agent.

41. **Pleurisy.**—Delafield has come to the conclusion that aspiration is the only treatment for pleurisy with effusion. He tabulates 200 ordinary hospital cases occurring in the years 1886 to 1901, with results. None of the patients died, none of them were injured by the operation, and in none of them was the chest infected. Of 200 cases 182 left the hospital entirely cured; 6 left the hospital within ten days after the aspiration, and probably recovered; 6 left at periods from 17 to 36 days, the pleurisy was better, but the results were uncertain; and 6 left the hospital at the end of from 24 to 38 days, not at all improved. In more than one-half of the cases the duration of the pleurisy before aspiration was between 10 and 30 days. In all the inflammation had been kept up and the patients had not been at all improved either by Nature or by the different medicines which they had taken. The operation was done once in 142 cases, twice in 45, three times in 9 cases, and four times in 4 cases, and the length of time intervening between aspiration and entire recovery ranged from one week to six, a larger number taking a longer time. In private practice he says the results are generally better than in hospitals.

42. **Pancreatic Lithiasis.**—The literature of this condition contains six cases where a positive diagnosis of pancreatic lithiasis was made or suspected during life. Abstracts of these and of a case of his own are given by Kinnicutt. He remarks, in conclusion, on the difference from cholelithiasis, and says none of the subjective symptoms, such as nausea, vomiting, diarrhea, etc., can be regarded as characteristic. The belief that a ptyalism of varying degree accompanies a deficient secretion of the pancreatic juice, either through occlusion of the ducts or disease of the gland, is not borne out by clinical experience. The pain probably differs neither in kind nor location from that of cholelithiasis. The presence of an unusual number of undigested striated muscle fibers in the stools can not be regarded as a basis for positive diagnosis, but its presence is suggestive. The decisive evidence of the existence of pancreatic lithiasis is the recovery of the characteristic concretions from the stools, and is exceedingly rare. If the other

symptoms fail to furnish evidence singly, their various combinations may be suggestive. Attacks of epigastric colic of an obscure nature, with or without jaundice, associated with a large number of muscle fibers in the stools, accompanied or followed by glycosuria, should be regarded as a reasonable basis for a diagnosis of pancreatic lithiasis.

43. **Wolff's Law.**—Wolff's law is translated by Freiberg as follows:

Every change in the form and function of the bones, or of their function alone, is followed by certain definite changes in their internal architecture and equally definite secondary alterations of their external conformation, in accordance with mathematical laws.

He discusses its applicability, having studied the bony structure of various animals, including the primates, and also pathologic cases. He says in conclusion that from all the researches of Wolff, Zschokke, Schmidt and others, as well as from observations herewith presented, it is believed justifiable to conclude as follows:

1. The strictly mathematical concept of Wolff's law has not yet been justified by demonstration. 2. Save in their mathematical aspects the statements of Wolff's law and its corollaries may be accepted as being in agreement with observations hitherto made. 3. If we accept the foregoing statements it does not follow that we must make use of the so-called "functional methods" in our therapeutic endeavors; they are to be chosen not from theoretical considerations only, but for reasons of expediency and practicability.

44. **Wolff's Law.**—Taylor discusses the same subject, concluding that we must all fully concur with Wolff that pressure does not produce atrophy in bone as Lorenz has claimed, and that functional transformation of bone must and does occur to meet the altered static demands of pressure, tension and shearing strain. He is not, however, prepared to admit that we can attribute all deformities to function alone, regardless of superincumbent weight. He supports his views by illustrations of deformities following mal-union, Pott's disease, etc.

45. **Talma's Operation.**—From a view of the facts ascertained and a study of the cases reported, Greenough concludes that the condition known as biliary cirrhosis with enlarged liver, jaundice and fever and without ascites, is accompanied in a certain proportion of cases by infection of the bile ducts. The drainage of the bile ducts by cholecystostomy is a proper operation when such evidence of infection is present, and symptomatic treatment has failed to relieve. Of 105 cases of liver cirrhosis which presented the symptoms of ascites, 42 per cent. were improved and 59 per cent. not improved by Talma's operation or one of its modifications. The mortality within thirty days was 29.5 per cent. Nine cases were improved in health two years after the operation, these presenting no marked differences in general character from the others. Cases where the liver was enlarged gave a lower mortality and a higher percentage of improvement than cases of atrophic liver. Cases of suture of the omentum between the layers of the abdominal wall gave a lower mortality and a slightly higher percentage of improvement than cases where only peritoneal surfaces were brought in contact. Drainage increases the danger of sepsis and peritonitis and should be avoided. Tapping may be done, if necessary, after the operation. The presence of adhesions and perihepatitis is of good prognostic import as regards the success of the operation, while the number of tappings before operation and the presence of edema of the feet and legs are of less prognostic importance than the general condition of the patient, the size of the liver and the functional activity of the liver cells. Talma's operation or one of its modifications is of proved benefit in a certain limited number of cases of liver cirrhosis, primarily for the relief of ascites, and secondarily for the relief of other symptoms of portal congestion. The dangers attending the operation are mainly due to the weakened resistance of the patient, rather than to the operation itself. More judgment should be exercised than has hitherto been the case in the selection of cases. The operation is not indicated in ascites due to other causes and is contraindicated in the presence of renal or cardiac disease, and when evidence does not exist that sufficient functional liver tissue remains to maintain life. It is also contraindicated when complications exist sufficient in themselves to make the results of operation uncertain. The paper concludes with a summary of cases and bibliography.

49. **Serumtherapy.**—Packard and Wilson describe the theory of immunity and serumtherapy, defining the terms lateral-chain theory, complements, immune bodies, haptophore, toxophore, etc., and discuss the investigations that have been made. The principal purpose of their paper is to review the clinical evidence for and against the efficacy of sera in different diseases where they have been employed. The value of antidiphtheria serum is an established fact. The antitetanus serum, they conclude, is a valuable means of treatment, though by no means curative in all cases. It is only by a consideration of a large number of cases that its real value is discovered and its influence appears to be appreciable mostly in cases of subacute and chronic type, the mortality in the acute cases being less affected, though there has been a real reduction even there. Until very recently the development of a typhoid antitoxin seems to be even less encouraging than that of the antitetanus serum, but it now seems to promise significant help in the treatment of the disease; not only treatment of the disease itself with curative serum, but preventive inoculation has proved of value. The antistreptococcus serum, the authors conclude, will at least do no harm, and where special streptococci are involved alone, will eliminate the micro-organism, and control the symptoms unless used too late. When the streptococcus occurs in combination with other micro-organisms it has no effect, except so far as the streptococci are concerned. The antipneumococcus serum seems to be of less substantiated value, but we have apparently better results with the more active sera used in larger doses. Antiplague serum has yielded important and favorable results that have not been appreciated in this part of the world, and has a positive value in the treatment when properly employed, but the extent of its value is still an unsettled one. The serum treatment of tuberculosis, they conclude, is an adjuvant which if used early may result in cure, and when used late may retard the process and promote healing. The promise for it is good when we learn more definitely just where it can be employed with benefit. Other serums known are the antivenene, which seems to be of value, more particularly against certain forms of snake venom. Its action is directed against the nervous rather than the irritating and tissue-destroying principle in the venom. Anticholera, antidysentery serum, and the antitoxin of scarlet fever are also noticed. There seems to be as yet nothing that will touch malaria, but there have been some good results in such diseases as syphilis, whooping cough, erysipelas, anthrax, scarlatina, etc. In conclusion they refer to Emmerich and Low's "immunizing and curative proteidin," but say that no comment can be made at this time on the value of the product. The paper concludes with an extensive bibliography.

52 Appendicitis. John Bruce Harvie.
53 *Medical Gynecology. John H. Fuller.
54 A Case of Absence of the Uterus and Ovaries. Antonio Bustillo-Llrola.

51. **Polyhydramnios.**—Polyhydramnios is understood as the condition in which more than two pints of amniotic liquid existed at full term. The pathology is not fully known. The placenta is often large, dropsical, infiltrated, the umbilical vessels are often enlarged, and the amnion and chorion may be thickened with extensive fissures in the epithelial layer of the amnion and fatty degeneration of the cells. Any fetal condition leading to venous engorgement tends to produce polyhydramnios, and the irritating substances formed in the lymphatics may cause this condition. Excessive secretion from the cerebrospinal canal of the fetus may contribute to polyhydramnios. It does not follow increased renal action of the fetal kidneys. Davis thinks that further knowledge regarding the osmotic properties of maternal and fetal blood and of liquor amnii may be obtained through cryoscopy. The diagnosis is made by first diagnosing the pregnancy, but it may complicate ectopic pregnancy. In ovarian cyst the illness is longer and swelling at first unilateral; the uterus is but little enlarged. In ascites the dulness changes when the position of

the patient is altered. The diagnosis must be made further from hydatid mole, plural pregnancy, etc. All may mislead, but hydatid mole is accompanied with a pear-shaped uterus with little fluctuation, and there is blood discharged. In exceptional cases, ovarian cyst complicating pregnancy may be difficult to diagnosticate and exploratory incision may be necessary. The absence of tension on the membranes and of shortening of the cervix should be noted. Treatment by drugs is useless. If distension increases too rapidly and health is impaired, the cervix should be dilated under antisepsis, the membrane ruptured and fluid allowed to escape very gradually until the presenting part descends firmly against the cervix. Firm pressure must be made over the abdomen by a broad bandage and the patient watched, as labor is often precipitate and presentation unfavorable. Labor should not be hurried in the interests of the child because the fetus is often deformed, and there is increased danger of sepsis and hemorrhage to the mother. The uterus should be completely emptied and made to contract, and the hypodermic use of strychnia and ergot and other stimulation are necessary, while a hot 1 per cent. douche of lysol and tamponing with iodoform gauze may be required.

53. **Medical Gynecology.**—Fuller reviews the symptoms associated with pelvic disease. Nervousness is often relieved by sudorifics, and is often connected with weak heart and relieved by proper tonics. The headaches may depend on various causes, constipation, lacerated perineum, cardiac weakness, stomach disorders, etc., all of which can be relieved. Backache is another symptom. This, if dorsal, depends most on the stomach and the liver; if sacral, on the pelvic organs; if lumbar, on the bowels and kidneys. The respiratory disorders like chronic rhinitis and pharyngitis are those produced by imperfect excretion and a brisk purge will relieve them. The "winter cough" of gynecologic patients is often relieved by treatment of the kidneys, being due, he thinks, to renal insufficiency. Autointoxication from the digestive tract is also mentioned. The reabsorbed, resecreted and re-excreted bile carries an immense amount of excreted matter through the liver. Too great abundance of uric acid, leading to nervous and artheromatous symptoms is to be considered by the gynecologist, and renal insufficiency is often of more importance than the metritis or menstrual derangement, as many pelvic troubles run back to this causation. Fuller remarks that surgical technic is taught in all its refinement, but the symptomatology, differential diagnosis and medical part of gynecology does not receive adequate attention.

57 *Pneumonia, from the Bacteriological Standpoint. A. C. Abbott.

55. **The Pancreas in General Medicine.**—Stengel's article reviews the more recent acquisitions to our knowledge in regard to the pancreas in health and disease with special reference to the diagnosis of its morbid conditions. He considers fatty diarrhea an important symptom in connection with others, especially when there is no jaundice, but its absence is less significant. The pancreas is not essential to fat absorption though an important organ for this function. The finding of muscle fibers in the stools is of comparatively little value by itself, but has considerable significance if bile secretion is normal and gastrointestinal disease can be excluded. The relation of the pancreas to glycosuria is discussed at length by the author, especially the relation of the islands of Langerhans; the recent researches on this point are noticed, especially those of Opie. He says, while the results of recent studies tend to more and more magnify the importance of the pancreas in diabetes, it can not be said that it always plays a part. Special points in the diagnosis are noticed at length: emaciation, fatty diarrhea, lipemia and lipuria, sialorrhea, which is not very frequent and less significant in pancreatic than gastric disease, the subjective symptoms of pain and its character, glycosuria, etc.

58 *The Pretubercular State—Some of Its Etiologic Factors. A. P. Buchman.
59 The Lesson of Virchow's Life. James J. Walsh.

58. **The Pretubercular State.**—Buchman sums up his ideas by saying that every case of tuberculosis, no matter where located, has a clearly-defined pretubercular state of considerable duration, and that the conditions which initiate this are in positive relationship with tuberculosis. That the primary and sole cause of the pretubercular state is: 1, an excess of carbon in the system, and 2, unelaborated food particles floating in the general circulation. That a properly and scientifically regulated dietary will, in a large proportion of cases, entirely cure the condition, hence the importance of the dietary in the prophylaxis of tuberculosis.

64 *The Cecum: In Relation to the Psoas Muscle in 310 Adult Male and 125 Adult Female Autopsies. (Concluded.) Byron Robinson.

60. **Eczematoid Dermatitis.**—Engman describes and illustrates this condition and reports cases. He finds it generally starts from a trauma or infection, often after surgery or an accidental wound. The similarity between this rapidly-spreading condition and Crocker's dermatitis repens is at once obvious. Its infectiousness was beautifully illustrated among the babies at the Bethesda Foundlings' Home during the summer of 1900. The pūre impetigo type is far more infectious and more prevalent than the dermatitis. The infection is usually staphylococcal. According to his studies pure cultures of yellow or white staphylococci, or both, can be obtained from the contents of the initial vesicles, serous or seropurulent discharge, crusts and denuded surfaces of the skin. When the apparently-healthy skin of a person suffering from eczematoid dermatitis is slightly irritated after sterilization, and inoculated with the discharge, the flora and symptoms of the original from which the inoculation was taken are reproduced. Inoculation experiments from individual to individual have not been encouraging, probably on account of the patients' unwillingness. Inoculations from artificial cultures on individuals were not very successful. Engman thinks the organism must undergo some change in its chemotactic character in artificial media. The suppuration so often associated always contains staphylococci, and all these facts together confirm his belief in the staphylococcic origin of the disorder.

61. **Antipyresis in Children.**—The urgency of antipyresis depends on the concomitant symptoms, and not on the height of the mercury alone, but Saunders thinks that even moderate temperature in comparatively mild disease should not be entirely disregarded if suffering is caused. Hydrotherapy takes first place in its relief, but in many cases it is advantageous to combine the external and internal antipyretics. This combined method is not sufficiently employed. He does not object to the use of coal-tar products, if given occasionally with full recognition of the fact that they are depressing in their action. They are contra-indicated wherever the heart is liable to fail, as in diphtheria and pneumonia, though in the early stages of scarlet fever and other exanthemata they are not harmful, and the relief they afford will generally justify their use. In influenza some cardiac stimulation should be added. He calls attention to the value of pilocarpin as an eliminant and antipyretic in diphtheria and scarlet fever. In pneumonia, veratrum viride is the safest antipyretic and its general neglect is undeserved. The external application of guaiacol is another antipyretic; just how it acts is still unsettled. He has found it exceedingly valuable in infants and children, for in pneumonia many cases do not bear cold baths well, and then the external application of this drug is indicated. In typhoid fever and especially in tuberculosis there should be no hesitation in its use. With care there is little danger of its producing depression. In some cases one drop is sufficient, in others several are required.

Hydrotherapy should be employed with judgment in its application. Some children take the full bath nicely, and others become very chilly and do not react promptly. For general use the wet pack is most likely to agree.

62. **Summer Diarrhea.**—From a recent study of the disorder in the Bethesda Foundlings' Home, Zahorsky found the Gruber-Widal reaction in a large proportion of cases and the *Bacillus dysenteriæ* was obtained. There will be little doubt, he thinks, that the epidemic depended on this bacillus, and he believes that while we can not exclude other germs this must be considered the probable etiologic micro-organism.

63. **Bacillus Dysenteriae.**—Fisch thinks it is too early to form conclusions as regards Duval and Bassett's discovery, but seemingly there is a relation of the bacillus to a great number of intestinal infections of infants. In Zahorsky's studies the number of positive reactions was rather puzzling, and in a few tests of the blood from healthy infants the results were always negative. He thinks that under the head of summer complaint a number of etiologically different conditions are gathered, but that Duval and Bassett have succeeded in clearing up a part of the question.

64. **The Cecum.**—This number contains only the conclusions of Robinson's article; they are too long to be reproduced. The reader is referred to the original.

Kansas City Medical Index-Lancet.

December, 1902.

65 *Suspension in Tabes Dorsalis. Harold N. Moyer.
66 *Plastic Surgery in Ophthalmology. Flavel B. Tiffany.
67 *Septicemia and the Curette. H. Plympton.

65. **Suspension in Tabes.**—Moyer concludes that suspension is not a cure but a valuable aid in tabes. It is useful in about 30 per cent. of cases. Rapidly progressing or stationary cases are least benefited; those of moderate severity where the disease is largely confined to the lumbar enlargement, receive the most benefit. If the cervical enlargement is most involved, little can be expected from this measure. The method should be adopted with care, and the effect of each suspension be closely observed.

66. **Plastic Surgery in Ophthalmology.**—Tiffany reports cases of operations on the eyelids for trichiasis, entropion, etc.; gives illustrations and calls special attention to the operation of skin grafting for the restoration of the destroyed lid, and the operation for congenital ptosis.

70 Nose and Throat Work for the General Practitioner. George L. Richards.
71 The Surgical Assistant. Walter M. Brickner.
72 A New Method of Preventing Shock, Nausea and Thirst After Operations. T. J. Biggs.

68. **Surgical Patients.**—The points made by Ochsner in his general consideration of surgical cases are the avoidance of unnecessary operations, and the necessity of careful examination without, however, too great insistence on positive diagnosis, when it may require operative measures that might be dangerous. He thinks that the exploratory examination of malignant tumors is sometimes overdone. He also protests against any kind of diagnostic massage or pressure on suspicious growths as likely to do damage, also against too much faith in the exploratory needle and the syringe since they are unreliable. In considering the patient in regard to the advisability of an operation, a number of things must be taken into account. Old age is not of itself a contraindication, though elderly patients do not bear the loss of blood so well. Old people generally bear surgical operations well if they are allowed to move about and sit up early after the operation. He thinks it may not be bad even in apparently serious operations, such as removal of the breast, to allow the patient to sit up the next day. Obesity is a point that requires consideration, but seldom entirely contraindicates operation. Tuberculosis is not a contraindication to operation for the removal of tuberculous growths. Cachexia in malignant growths is, as a rule, a distinct contraindication, exception being made in cases of ulcerative carcinoma where the cachexia is due largely to the absorption of decomposing products. The question of time is also considered, and the need of expedition should not prevent thorough and careful work. On the other hand, prolonging the operation may be disastrous, and prolonged anesthesia is dangerous and infection is more likely to occur. He protests alike against insane haste in performing operations and imbecile deliberation; it is difficult to say which is the worse. The operation should include a minimum of traumatism and there should be the least possible manipulation of tissues.

Nashville Journal of Medicine and Surgery.

November, 1902.

73 *The Therapeutic Value of Heat and Cold Applied to the Spinal Column. W. Frank Glenn.

73. **Heat and Cold Applied to the Spinal Column.**—Glenn emphasizes the importance of heat and cold as applied to the spinal column in treating various conditions. He has brought on the suppressed menstrual flow by the application of ice to the lower dorsal and lumbar region, and has arrested uterine hemorrhage by hot-water packs at a temperature of 115 to 120 over the same tract. He has also seen congested lungs readily relieved by hot-water applications over the lower cervical and upper dorsal spine, and fever, he says, can be absolutely controlled by the application of hot water over the cord from the fourth cervical to sixth dorsal vertebra. His view is that nothing should be put into the stomach except such substances as form a component structure of the body, and if this rule were followed we should have no digestive disorders, and always have a normal blood, and since the amount of blood in any part is controlled by the action of the vasomotor centers in the cord and the sympathetic ganglia in close proximity to the cord, any disease causing local circulatory disorder can be thus located and treated. To get the proper effects of heat and cold applied to the cord, the anatomy and physiology of the nervous system must be scrupulously borne in mind.

18 La legislation sanitaire industrielle en France et à l'étranger. Ibid.

2. **Examination for Typhoid Bacilli in Water.**—Busquet describes experiences which prove that the typhoid bacillus may be found in the mud or slime at the bottom of wells, cisterns, sluggish streams, etc., after it can no longer be found in the water above.

4. **Danger from Raw Vegetables and Fruits.**—The Public Health Society, of which the *Annales* is the organ, adopted resolutions appealing to the authorities to absolutely prohibit on sewage farms the raising of vegetables and fruits which are eaten without cooking.

13. **Certain Causes of Sudden Death.**—Stoenesco relates a number of instances from his extensive experience of sudden deaths from unusual causes. In a few cases, suffocation was caused by an intestinal worm. In one case a footman vomited, but for fear of soiling the floor retained the vomited matter in his mouth and a deep inspiration drew it into his lungs. Fragments of the vomit were found in remote ramifications of the air-passages. In another case unsuspected pneumonia caused the sudden death of a bridegroom. Four men cleaning a vault succumbed suddenly to acute suffocating catarrh. In two cases a hydatid cyst or tubercular tumor in the left ventricle was the cause of death; in others spontaneous rupture of the heart or of an aneurism while the subject was quietly walking or writing, and in ten cases death was the result of a perforating ulcer in duodenum or stomach which had been unsuspected. In others, a large calculus impacted in the bile duct; rupture of enlarged heart in a slight accident; hemorrhage from varicose veins in a pregnancy nearly at term, or retention of urine in a man with hypertrophied prostate and dilatation of the ureters. The statistics at Bucharest show that renal lesions are responsible for about 50 per cent. of all cases of sudden death.

24 (No. 44.) Tennis Arm. Clado.
25 (No. 45.) Students' Number. Medical Guide to France and her Colonies.—Numero des Etudiants.
26 (No. 46.) Sur la transmissibilité de la fièvre aphtheuse, stomatite aphtheuse, des animaux à l'homme (from animals to man). H. Roche.
27 (No. 47.) *Myopathie du tétanos. Urriola (Panama).
28 (No. 48.) Illustrated Description of New Académie.—La nouvelle Académie.

20. **Biliary Cholelithiasis.**—Zalackas reviews 36 cases of fistula, the result of gallstones. Expectant treatment in 12 failed to prevent the death of 5, while all the cases treated by surgical intervention were promptly cured, with one exception.

21. **Study of Red Corpuscles with Iodin Solutions.**—Distefano describes his experiments, which have led him to the conclusion that regeneration is occurring whenever the microcytes in a weak solution of iodin are of normal aspect and numbers. He has found that the best formula for the solution is 18.75 gm. metallic iodin; 37.5 gm. potassium iodid and 300 c.c. of distilled water. The reaction to this fluid of the red corpuscles varies with their size, and he accepts that the smaller cells are the youngest, consequently the presence of numerous small cells is evidence that regeneration is proceeding more or less normally.

22. **Relations Between Typhoid Fever and Insanity.**—In two cases in Paris' experience at a large insane asylum melancholia in women predisposed by heredity and privations or emotions passed away with an intercurrent typhoid fever, and the patients recovered from both at the same time. The stimulation of the functions of assimilation evidently restored the normal balance during convalescence from the fever. Two other similar cases were temporarily improved, but the melancholia returned after convalescence. There was a substratum in these cases of serious climacteric circulatory disturbances. He also noted that maniacs in many cases recovered their reason during the height of the typhoid fever, and had no febrile delirium. This never occurred in subjects who were congenitally degenerates. Delirium occurred in the latter under the influence of typhoid fever as in otherwise normal subjects. This fact may serve as a basis for physiologic study of the differences between true degenerates and the delirious insane. Hygiene and therapeutics offer better prospects in the treatment of the latter than of the former. Typhoid febrile delirium, therefore, of the ordinary type, indicates that the subject was previously normal or merely a simple degenerate, and is not actually insane. The hallucinations and mania of true insanity diminish temporarily under the influence of the typhoid fever, as also the convulsive manifestations and psychic troubles of epilepsy. These facts should be borne in mind when committing a person to an asylum, as an unsuspected typhoid condition may mask the true diagnosis. Post-typhoid mental disturbances are of the type of cellular degeneration, rather

than of actual insanity. The mental condition resembles the mental debility observed in certain cases of hemiplegia, syphilis, etc. In short, typhoid fever may transiently improve and sometimes cure certain mental affections, but can never be the cause of this same type. The type affected is that in which hereditary influences are the basis for loss of mental balance in case of privations, emotions, debauch, alcoholism, emotional stress, or other accidental physical disturbance.

27. **Myopathy from Tetanus.**—Urriola's patient was a field hand of 34, exhibiting a typical case of myopathy with "clasp-knife rigidity" and progressive atrophy. The condition followed a severe attack of "spontaneous tetanus" six years ago.

30. **Permanent Results of 800 Bassini Operations.**—Goldner reviews the results achieved at the clinic of the late Professor Albert of Vienna, and notes that primary healing is not the only deciding factor for the ultimate outcome. There was recurrence of the hernia in 35 cases; suppuration occurred in only 10 of these. In 3 the muscles seemed to be defectively developed, and in 5 there was senile alteration. In 2 the local anesthesia may have been responsible, as it possibly interfered with suturing. In 4 nothing could be discovered to explain the recurrence. In 3 cases a femoral hernia developed after a radical operation on an inguinal hernia. In 9 of the cases of recurrence severe work was resumed in three weeks. He advises waiting three months when possible, and believes that the absence of early severe work is the reason why the operation is more apt to be successful in children. Three of the patients died, one during the narcosis and 2 from embolism. Both of the latter had large varices on the legs, and this condition should impose caution in doing a radical operation.

32. **Blood Cyst in Skull.**—Franke's patient was a young woman, and the cyst owed its origin to a congenital hole or fissure in the skull. There was probably merely a congenital varix at the spot at first, but as it grew it enlarged the hole and the edges of the bone were absorbed. After the copious hemorrhage had been arrested by inserting the finger in the hole and then tamponing, he completed the operation by introducing a piece of silver-wire netting, about 4 by 8 cm., beneath the skin, draining and suturing.

34. **Results of Operative Treatment of Carcinoma of Large Intestine.**—Hochenegg compares his results with those obtained by other surgeons, and thinks that they confirm the benefits of his sacral method of extirpating a carcinoma in the rectum. He has had 237 such cases and operated on 174; 158 were cured, and only 16, or 9.12 per cent., died. Czerny's mortality has been 10 per cent.; Krönlein's, 12.1; Mikulicz's, 25.7; Kocher's, 28.5; Bergmann's, 32, and König's, 32.5 per cent. Hochenegg states that he lost none of his patients from the narcosis, from hemorrhage during or soon after the operation, from shock or collapse, nor from post-operative pneumonia, while the reports of others attribute about 50 per cent. of the mortality to one or more of these causes. He warns that a diarrheic stool is much more poisonous than a formed stool, and hence denounces the practice of administering a purgative before operating. He operated by the perineal route in 8 cases and by the sacral in 112. Thirty, or 25 per cent., of these 120 patients are alive to-day after a minimum of three years. Ten of the 30 are completely and 2 comparatively continent. The others have a sacral anus and are incontinent. He calls the year after the operation the "quarantine year" as progression of the lesion is revealed within this time by sacral pains, emaciation, etc. He operated on 194 out of the 283 cases of cancer of the intestines that have come under his observation. The total mortality has been 24, and 170 have remained cured to date. In 30 the intervention was merely palliative.

36. **Course of Ileus in Carcinoma in Intestines.**—Anschütz mentions that in 14 out of 26 cases the ileus developed without premonitory symptoms and the assumed volvulus proved to be a carcinomatous lesion. He calls attention to the localized meteorism observed in the cecum in case the carcinoma is located low down and the ileocecal valve is unusually resistant. The local distension of the cecum is an aid to diagnosis, but it is always a bad sign when very pronounced.

39. **Post-Operative Hydrocephalus.**—Muscatello has found that secondary hydrocephalus occurring after surgical intervention is usually due to syphilis and can be cured by specific treatment combined with repeated evacuation of the fluid. A suppurative process occurring in cases of spina bifida is almost certain to be followed by meningitis or hydrocephalus, which in this case is due to pyogenic infection, and has a grave prognosis.

44. **Involvement of Lymph Glands in Carcinoma of Pars Pylorica.**—Twenty cases of carcinoma of the pyloric portion of the stomach observed at Mikulicz's clinic were carefully scrutinized, and only one case was found entirely free from

some metastasis in the glands of the region. About 189 glands were examined, and 110 were found sound, but others at a distance were affected. By removing all the small omentum the glands in it are extirpated at the same time, and there have been no indications of gangrene or other disturbance from inadequate blood supply in his experience. The glands in the lesser curvature were found involved more frequently than those in the greater curvature. In only two cases were they exempt, and 50 per cent. were affected.

46. **Natural Means of Alleviating Pain.**—Ritter makes the announcement in this article that he has established by his research that the pain from a serous effusion is not caused by the mechanical action of the fluid but by its concentration. The constant destruction of albumin produces rapidly a very concentrated fluid, which causes intense pain, but as more serum mixes with it, the pain diminishes as the dilution increases. The concentration of the fluid is evidenced by the variation of the freezing-point. It averages normal in the pus of a cold abscess, but may be .715 C. in empyema pus, etc. Bier has called attention to the fact that his methods of inducing artificial hyperemia or venous congestion reduce the pain to a marked degree. Ritter shows that this alleviation of the pain is due to the dilution from the hyperemia or venous congestion in the concentrated effusion. We must assist Nature in this process of dilution, and we will be able in this way to systematically alleviate pain. He has been most gratifyingly successful in the application of these principles to the treatment of severe, painful burns, inducing venous congestion, according to Bier's directions. (See THE JOURNAL, xxxviii, p. 1113.)

48. **Functional Tests of Kidneys.**—Straus confirms the fact that under physiologic conditions the kidneys work alternately and exactly alike. He describes two cases in which a carcinoma or ulceration had destroyed almost the entire parenchyma while the glomeruli were still intact. The phloridzin test had been positive, to a slight extent, which indicates that the glomeruli may be regarded as the seat of the transformation of phloridzin.

49. **Experimental Ligation of Portal Branches.**—Ehrhardt found that the disturbances induced in the liver by ligation of large branches of the portal vein were merely transient. The shriveling and ascites noticed soon became compensated by the regenerative forces of the organ and the establishment of collateral circulation.

53. **Treatment of Generalized Peritonitis.**—Friedrich was able to save all his ten patients with generalized peritonitis traceable to appendicitis or traumatism, and he attributes his success to his method of draining and of subcutaneous nourishment. He remarks that anaërobic bacteria are probably involved in the process more than is generally appreciated. He drains with a special trocar inserted through the abdominal wall, and passed behind the uterus and out through the vagina. A drain tube is hooked on the trocar guide and is then drawn in by the latter until it emerges in the space behind the uterus, while the shell of the trocar is held at the entrance to the vagina. The drain tube is thus brought into the exact point in the Douglas where most needed, and without the slightest scraping of the walls of the vagina. The shell can then be removed. He injects 30 to 100 or even 150 c.c. of olive oil, leaving the canula in place and injecting it always at the one point. It is absorbed in less than an hour.

59. **Surgical Disinfection.**—Braatz announces that warming gauze to 60 C. has no effect on its further disinfection, and that superheated steam—at 110 to 122 C.—does not permeate the gauze. The disinfection is most complete when the gauze is warmed beforehand to 88 C. and then exposed to steam at 100 C. The gauze takes up the steam under these conditions, but must be kept in a wire frame away from the walls of the receptacle. He proclaims that steam sterilization as usually done is ineffectual.

62. **Invagination of Intestines.**—Haasler advocates resection far into sound tissue as the only safe way to treat an invaginated loop. In his 10 cases the invagination was traceable to a tumor in the intestinal wall in 3; to adhesions left after appendicitis in 2, and to a tuberculous lesion in one. He also reviews 133 cases which he has collected.

70. **The Circulation and Local Tuberculosis.**—In Friedländer's experiments animals inoculated in the femoral artery, with a suspension of charcoal dust, lime, lycopodium, or other substances, including weakly virulent cultures, developed local processes at the very points which display a predisposition for local tuberculosis. Even in physiologic conditions the current is peculiarly sluggish and the walls of the vessels exceptionally thin at these points, evidently favoring the deposit of foreign particles and of bacteria.

Centralblatt f. d. Grenzgebiete der Med. u. Chir. (Jena), v.

72 (No. 20.) *Acuter und chronischer Gelenks- (articular) Rheumatismus, Entstehung (origin) und Beziehung zu anderen Gelenks- (and relations to other joint) Affectionen. W. Predtetschensky. (Commenced in No. 17.) Critical Review.

73 (No. 22.) *Ueber die Erkrankungen der Mesenterialgefässe (vessels) und ihre Bedeutung (significance) für die Chirurgie. W. Neutra. (Commenced in No. 18.) Critical Review.

72. **Study of Articular Rheumatism in Relation to Other Joint Affections.**—In this communication from Moscow forty-six of the latest articles on articular rheumatism are reviewed, including a number of Russian works. The writer first points out the incongruity of the term "rheumatism" from rheuma, a flux, as applied to many joint affections. Physicians usually content themselves with the term "rheumatic" as meaning an affection due to getting chilled, but late researches demonstrate that this is very unscientific and entails confusion. They should trace the joint affection to its actual cause. When this is done it will be found that a new classification is necessary. The term "chronic rheumatic polyarthritis" will be reserved for the chronic multiple joint affection in which there is known to be an unmistakable connection with acute articular rheumatism. The cases which have been hitherto labeled chronic articular rheumatism but whose origin is obscure will be classed as chronic polyarthritis without any descriptive term. This is certainly better than to ascribe to rheumatism cases which have nothing in common with it except the external appearance. Acute articular rheumatism very rarely passes over into the chronic form, and consequently the number of cases of true chronic rheumatic polyarthritis will be found very small. The domain of progressive deforming polyarthritis will contain besides the essential polyarthritis deformans and malum senile coxæ, the varieties which have been known as polyarthritis chronica villosa hyperplastica, many cases of nodular rheumatism, and some of Haberden's nodules (others will be found to belong in the class of uric polyarthritis). As the physician learns to trace the connection between the polyarthritis and various infections he will distinguish between the true rheumatic acute and chronic polyarthritis and the gonorrheal, the erysipelatous, the typhoid and the pneumococcous. Possibly also the scarlatinal, dysenteric, tuberculous, syphilitic, the neurogenic (in case of tabes and syringomyelia), the polyarthritis accompanying osteoarthropathy of Marie-Bamberger, and polyarthritis deformans progressiva, urica, and possibly also polyarthritis urica, syphilitica et deformans. This makes fifteen classes besides that of simple polyarthritis chronica.

73. **Affections of Mesenteric Vessels.**—Neutra reviews the literature on this subject and gives a brief summary of the various cases he has been able to find of occlusion of the mesenteric vessels, aneurisms and periarteritis nodosa. They include a number published in America. Occlusion of the mesenteric vessels is due to embolism or thrombosis, and the resulting alterations in the intestines range from mere hyperemia to gangrene, peritonitis, etc. The onset is usually sudden, violent pains around the umbilicus or in the epigastrium, hypochondrium or lower abdomen, diarrhea, and, in 30 per cent. of the cases on record, intestinal hemorrhages. Ileus is observed quite frequently later and distension of the abdomen. In 2 instances tumors could be palpated which proved to be accumulations of blood between the sheets of the mesentery. The prognosis depends on the establishment of collateral circulation, and treatment should aim to promote it. Light massage of the abdomen may be useful, as it enhances the local circulation and may break up the coagulum. This treatment, with efforts

to raise the blood pressure, is indicated in the colic stage and on the appearance of intestinal hemorrhages. After symptoms of ileus have developed, all nonsurgical treatment is inevitably hopeless. Only a few cases have been reported in which operation proved successful, and these were all undertaken at the stage when the intestine was already dark colored but with no signs of gangrene or peritonitis. The cases on record number 120; in 86 the arteries, and in 32 the veins were involved. One-third of the patients were women. The age ranged from 5 to over 90 years, but the majority were in or past middle life. In 108 cases that terminated fatally, 29 seemed to run a slow, chronic course. The clinical picture of periarteritis nodosa is a characteristic combination of neuritic or myositic symptoms with gastrointestinal manifestations.

74 and 75. **Accouchement Force by Means of Metal Dilators.**—Knapp presents a dilator made on the principle of Bossi's, but which he thinks is a great improvement, as it is simpler and the action of the spreading lattice-work ring is more even and spreads over a larger surface than with the four arms of the Bossi dilator. The arms and the ring can be protected by rubber caps. Wagner reports fine results from the use of metal dilators, confirming the statements of Leopold and Knapp in regard to the great value of this method of delivery, especially in eclampsia, and that it should entirely supersede Cesarean section in such cases. He reports 3 cases, Bischoff 5 and Langhoff 2, in which a completely-closed portio was enlarged in twenty to thirty minutes by means of the dilator (Bossi's) with minimal hemorrhage and no injury to the parts. Mueller delivered a patient in twelve minutes by this means in narcosis and extracted a thirty-weeks' fetus. It is possible, he adds, to enlarge the os in eight minutes sufficient for version, and, with a little further dilation by the hand, immediate extraction of the child. He uses a dilator made on the principle of a glove stretcher, which seems to answer the purpose perfectly well, although he prefers his inelastic rubber bag or metreurynter when haste is not necessary. He states that it is possible under favorable conditions to accomplish the dilation with the latter in ten minutes without narcosis, and reports a case. Frommer illustrates a dilator, which he claims is superior to Bossi's, as the dilation is accomplished with eight instead of four arms, and they stretch the vagina as well as the os. When folded, the dilator looks like the frame of a closed umbrella, but when dilated by means of a screw in the handle and graduated scale, the instrument resembles the partially-opened frame of an umbrella, but with the handle emerging from the top. All the branches can be taken out to be sterilized separately.

76. **Surgery of Uterine Cancer.**—Franqué advocates the more general use of supravaginal amputation according to Schroeder in the treatment of certain cases of beginning cancroid of the portio, and states that patients operated on in this way by Hofmeier and himself are still well after six years. He also doubts whether the columnar epithelium cysts found in the pelvic glands in cases of uterine cancer should be regarded as metastatic. He has noticed them in cases of basement epithelium neoplasms without a trace of glandular degeneration in the primary tumor and also in a case which exhibited both these cysts and metastases of the carcinoma, but with no apparent connection between them. He has never yet found them in women free from cancer, but thinks they could be found with more extensive material. He mentions, in conclusion, a case of malignant chorio-epithelioma operated on more than seven years ago by vaginal total extirpation about four months after delivery and about three months after the first hemorrhages had been noted. The patient is in good health to date.

77 and 78. **Cervico-Vaginal Fistulae.**—Wormser adds another to the nine cases collected by Neugebauer. The patient was a young primipara in the fifth month. The posterior wall of the cervix tore spontaneously during the third day of labor, and the fetus was evacuated through the laceration. There were no venereal nor abortive antecedents. Dirmoser reports a similar case in the fourth month. The fistulæ in each were rebellious to various operative measures. They were both longitudinal, and while Wormser's patient was left sterile, Dirmoser's patient passed through a second abortion and then was delivered of a healthy boy through the fistula. The natural os was impermeable.

79 and 80. **Vaginal Cesarean Section in Carcinoma of the Portio.**—Kallmorgen delivered twins in the eighth month of pregnancy by this means in a case of operable carcinoma of the portio in a v-para, 32 years old. The children died in the course of two weeks, but the mother made a smooth recovery, with very little hemorrhage. Weber delivered a healthy boy by this means, but the child succumbed a month later to acute gastritis. There was no shock nor appreciable hemorrhage. He has collected 13 cases of vaginal Cesarean section with portio carcinoma in the literature. Two of the patients were very weak and died from heart failure. All the others recovered. Nine of the children lived; some of them weighed more than 4000 gm. He recommends, therefore, Dührssen's vaginal Cesarean section as the standard procedure for cases in which beginning cancer of the portio is diagnosed at the close of pregnancy, with a normal pelvis and yielding soft parts.

81. **Lateral Symphysiotomy.**—Gigli's extramedian section of the pubis was described in THE JOURNAL, xxxix, p. 226.

82. **Scopolamin-Morphin Anesthesia in Obstetrics.**—Steinbüchel portrays the benefits derived from a harmless anesthetic which banishes pain for a few hours, attaining its maximum effect in one and one-half hours, without affecting the contractions of the uterus, injuring the child nor inducing consecutive atony of the uterus such as is liable to follow chloroform. He accomplishes this by the scopolamin-morphin method of anesthesia. The narcotic effect of the two drugs is superposed, while their other effects are apparently mutually neutralized. He injects at first half a syringeful, and after two hours a full syringeful. The dose was .0003 gm. of scopolamin and .01 morphin to the syringeful. With the exception of a brief period of excitement in one very nervous i-para, 42 years old, he never witnessed the slightest by-effects from this method of anesthesia in his extensive experience. If necessary, a few whiffs of ether or chloroform may supplement it in case long surgical intervention is required.

99. **Calomel in Pediatrics.**—Ladbiewski does not believe in administering calomel for a laxative, preferring castor oil for this purpose, but he expatiates on its almost marvelous action in flatulent colic, dyspepsia, febrile gastrointestinal catarrh, convulsions from indigestion, icterus, hydrops and syphilitic and scrofulous eye affections. He orders it always in the form of calomel ophthalmicus as the finest pulverized, and gives ten or twelve doses of .005 to .02 gm., according to age. He warns that traces of sublimate develop in the mixture of calomel and sugar in time, and hence it should always be made up fresh. Sunlight decomposes calomel. Salt and salted foods, bitter almonds and cherry laurel water, iodin and ammonium chlorid have a tendency to transform part of the calomel into sublimate.

103. **Infantile Eczema.**—Eczema in infants can be influenced by appropriate internal treatment of the digestive tract, and this fact distinguishes it from the purely ectogenic parasitic and artificial eczemas of older children. But secondary infection may modify it in infants and require external as well as internal treatment.

110. **Pneumococcus Peritonitis in Children.**—The encapsulated form recovers rapidly after evacuation of contents. The prognosis is more serious when the peritonitis is not encapsulated. Nine died and 3 recovered out of 12 cases collected by Stooss, including one personally observed, which recovered. He has also had 3 cases of the encapsulated variety.

111. **The Question of Congenital Rachitis.**—Escher was unable to discover any traces of rachitis in a number of fetuses and still-born children examined.

126 *Muskel-Syphilis im Frühstadium (early stage). R. Matzenauer. (Commenced in No. 10.)

120. **Naphthalan in Treatment of Eczema.**—A number of writers, including Unna and Hallopeau, have reported much clinical experience with naphthalan, establishing that it is an effectual means for treating certain cutaneous affections, not irritating to the tissues and borne well by nearly every skin, while it displays great energy in drying up secretions, alleviating pain, soothing the itching, promoting the regeneration of the epidermis and absorption of infiltrates.

126. **Early Syphilitic Myositis.**—Matzenauer announces that the involvement of the muscles in syphilis is liable to occur early, in which case the proliferating interstitial infiltrate spreads throughout the muscle in a diffuse form and does not form foci. This infiltrate may be easily and rapidly absorbed and complete restitution is possible. Later in the disease the diffuse infiltration is liable to become transformed into gummatous foci. He witnessed this transformation in one instance. He has also observed cases with a rapid, malignant course, in which the nodular infiltration was marked in the early stages. Eleven of his 13 cases of syphilitic affections of the muscles were myositis diffusa, and he has found 26 similar cases in the literature. In 22 the myositis developed in the first year after infection and in 5 cases later than four years afterward. In 24 the myositis was restricted to a single muscle; in 5 it was symmetrical, and in 8 in various muscles successively or simultaneously. Six of the 37 cases were of the early malignant form, and in 2 of these the early infiltration softened and required operative treatment. The process is essentially the same in both the diffuse infiltration and the later gummatous formation, as he shows by colored photographs of sections from four cases, one an autopsy discovery.

142 Elimination of Nitrogen and Uric Acid in Psoriasis. L. v. Zumbusch.—Ueber Gesammtstickstoff- und Harnsäure-Ausscheidung bei Psoriasis.

134. **Differentiation of Primary and Secondary Pleural Tumors.**—Sorgo states that when the fluid derived by exploratory puncture abounds in epithelial elements, it is suspicious of a neoplasm, but a hemorrhagic or chylous tendency or the presence of fat or glycogen is no evidence either for or against. The sediment should be examined both fresh and in hardened sections. The neoplastic nature of the affection is demonstrated by polymorphous epitheloid cells with large oval or irregularly-shaped nucleus, by polynucleated cells, by mitotic and amitotic segmentation of nuclei and cells, by large vacuolated cells and vacuolization of the cell connections. The protoplasm and the nucleus of the cells in the sediment from cases of carcinomatous pleuritis attracted attention by intense staining with polychrome methods, methylene blue or thiosin, and by the numerous variations in the tints. The sediment is more abundant in case of secondary carcinosis of the pleura. The finding of cylinder cells, glandular elements and vacuolized cells indicates positively metastasis in the pleura from a primary carcinoma in some glandular organ. He has had occasion to study two cases at Von Schrötter's clinic.

145 (No. 22.) *Quelques considérations sur la grande neurose et surtout sur la valeur sémeiologique de ses stigmates. E. Macris.

145. **Study of Hysteria.**—Macris has observed at Paris eight cases which he describes. All were typical examples of severe hysteria and all were cured by suggestion, yet none of them presented any of the so-called stigmata of hysteria. The heredity, anamnesis and symptoms rendered the diagnosis unmistakable, and it was confirmed by the prompt recovery under psychotherapy. The symptoms were those of astasia-abasia in one case, of dystasia-dysbasia in another, coxalgia in the third, rhythmic choreiform movements in a fourth, paralysis and coxalgia in the fifth, and paralysis or "grande hystérie" in the others.

165 (No. 39.) *La verdadera interpretacion de la pulsacion del pie (foot). S. Tatti.

148. **Tumors of the Brain.**—Ayerza describes a case of sarcoma of the base which he was able to relieve of the intense pain, cerebral vomiting, blindness and paralysis of the legs, by simple puncture and evacuation of a certain amount of cerebrospinal fluid. The relief was immediate and durable to the time of writing, with two repetitions of the puncture.

149. **Study of Excitability of Nerve Centers After Death.**—Alurralde states as the result of his researches on dogs that the excitability of the nerve centers does not disappear with the suspension of the last sign of life. This postmortem excitability lasts for a shorter or longer time in different animals, ranging from eight to thirty minutes, becoming shorter the lower the animal stands in the list of warm-blooded animals. The cells in the spinal cord possess the highest degree of this postmortem excitability. It responds only to powerful chemicals which irritate and act destructively on the protoplasm, consequently it is impossible to reproduce the movement a second time on account of the injury to the parts.

152. **Preliminary Injections of Artificial Serum in Abdominal Surgery.**—Bozetti prepared an anemic patient for ablation of a fibroma weighing 19 pounds, by daily subcutaneous injections of artificial serum for a month previous to the intervention. She bore the operation well, without vomiting once. Since then all the patients, about 100 in all, have been systematically treated in this way with preliminary injections of artificial serum before abdominal interventions. The aim sought was the suppression of vomiting, and it was accomplished in nearly all. The few exceptions displayed merely a slight nausea. The patients rest after the operation without being disturbed by vomiting, while urination is copious. About 500 gm. of the serum are injected each twenty-four hours for a day or two preceding the operation.

160. **Seashore Treatment of Surgical Tuberculosis.**—Since the foundation of a seashore sanatorium for debilitated children near Buenos Ayres, in 1897, about 60 with tuberculous affections of the bones or ganglia have been sent there. The best results were obtained in those cases which had displayed a marked tendency to recuperation before being sent to the sanatorium. The seashore is evidently by no means a specific, and the tuberculous lesions pass through their usual phases the same there as elsewhere. There is no doubt that the benefit of sea air for such cases has been much exaggerated. The tanned cheeks of the children conceal the pallor of anemia beneath. The chief benefit from these seashore sanatoria is to receive children debilitated from other causes, after protracted infectious diseases, etc., and by restoring them to robust health abolish the predisposition to the acquisition of tuberculous lesions later. The child should stay a year at least, and sea bathing should be prohibited as its inconveniences outbalance the advantages. Children with albuminuria, pulmonary or very advanced lesions should not be sent to such a sanatorium.

163. **Psychopathology of Criminals in Simulation of Insanity.**—Ingegnieros argues that the most abnormal criminals are the least disposed to resort to insanity as a defense of their crime. The possibility of simulation is in inverse ratio to the degree of psychic degeneration of the individual.

165. **True Interpretation of the Pulsation of the Foot.**—Tatti called attention in 1898 to the foot beat, as one leg is crossed over the other, and stated that it probably represents the sum total of the contraction and dilation of all the arteries in the leg, plus the variation in size of the leg under the influence of the changes in the circulation, and its tonicity and elasticity. In case of mitral or aortic insufficiency the tracing of the foot beat varies in a characteristic manner from normal. He appends the "podogram," as he calls it, of the pulsation of the foot in a case of traumatic aneurism of the femoral artery after extirpation of the sac and ligature of the artery. The fact that the pulsation was noted in both feet excludes the idea that it is due to the action of any one vessel, or to the constriction of the vessels at the knee. He has been studying it in criminals and states that in the agitation and excitement common under the circumstances a nervous element is superadded to the circulatory in these cases.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

SELECTED PAPERS ON OPERATIVE AND CLINICAL SURGERY. By the Late William Stokes, M.D., M. Ch. (Univ. Dub.); F.R.C.S.I.; Knt., Surgeon in Ordinary to Her Majesty Queen Victoria in Ireland. Edited by William Taylor, B.A., M.D. (Univ. Dub.), F.R.C.S.I., Surgeon to and Lecturer on Clinical and Operative Surgery, Meath Hospital and Co. Dublin Infirmary. With a Memoir of the Author by Alexander Ogston, M.D., Regius Professor of Surgery, University of Aberdeen. Cloth. Pp. 484. Price, 10 shillings. London and Dublin. Bailliere, Tindall and Cox. 1902.

A TEXT-BOOK OF DISEASES OF THE EYE. A Handbook of Ophthalmic Practice for Students and Practitioners. By G. E. de Schweinitz, A.M., M.D., Professor of Ophthalmology in the University of Pennsylvania, etc. Fourth Edition, Revised, Enlarged, and Entirely Reset. With 280 Text-Illustrations and 6 Chromo-lithographic Plates. Cloth. Pp. 773. Price, $5.00 net. Philadelphia and London: W. B. Saunders & Co. 1903.

MALARIAL FEVER: Its Causes, Prevention and Treatment, Containing Full Details for the Use of Travelers, Sportsmen, Soldiers, and Residents in Malarious Places. By Ronald Ross, F.R.C.S., D.P.H., F.R.S., Walter Myers Lecturer Liverpool School of Tropical Medicine. Ninth Edition, Revised and Enlarged. Cloth. Pp. 68. Price, $0.75. New York: Longmans, Green & Co. 1902.

LESSONS AND LABORATORY EXERCISES IN BACTERIOLOGY. An Outline of Technical Methods Introductory to the Systematic Study and Identification of Bacteria. Arranged for the Use of Students. By Allen J. Smith, M.D., Professor of Pathology in the University of Texas, Galveston. Cloth. Pp. 298. Price, $1.50 net. Philadelphia: P. Blakiston's Son & Co. 1902.

MEDICAL MICROSCOPY. Designed for Students in Laboratory Work and for Practitioners. By T. E. Oertel, M.D., Professor of Histology, Pathology, Bacteriology and Clinical Microscopy, Medical Department, University of Georgia. With 131 Illustrations, Some of Which Are Colored. Cloth. Pp. 362. Price, $2.00 net. Philadelphia: P. Blakiston's Son & Co. 1902.

A MANUAL OF MEDICINE. Edited by W. H. Allchin, M.D. Lond., F.R.C.P., F.R.S. Edin., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital. Vol. IV. Diseases of the Respiratory and of the Circulatory Systems. Cloth. Pp. 493. Price, $2.00 net. New York: The Macmillan Co. 1902.

TWENTIETH CENTURY PRACTICES. An International Encyclopedia of Modern Medical Science, by Leading Authorities of Europe and America. Edited by Thomas L. Stedman, M.D., New York City. Volume XXI. Supplement. Cloth. Pp. 845. Price, $5.00. New York: Wm. Wood & Co. 1903.

THE MATTISON METHOD IN MORPHINISM. A Modern and Humane Treatment of the Morphin Disease. By J. B. Mattison, M.D., Medical Director, Brooklyn Home for Narcotic Inebriates. Cloth. Pp. 40. Price, $1.00. Published by the Author. New York: E. B. Treat & Co. 1902.

MANUAL OF ANTENATAL PATHOLOGY AND HYGIENE. The Fetus. By J. W. Ballantyne, M.D., F.R.C.P.E., F.R.S. Edin., Lecturer on Midwifery and Gynecology, Medical College for Women, Edinburgh. Cloth. Pp. 527. Price, $5.00 net. New York: Wm. Wood & Co. 1902.

OBSTETRICAL NURSING FOR NURSES AND STUDENTS. By Henry Enos Tuley, M.D., Louisville, Ky., Professor of Obstetrics, Kentucky University, Medical Department. Cloth. Pp. 202. Price, $1.00 net. Chicago: G. P. Engelhard & Co. 1902.

A TEXT-BOOK OF NURSING, for the Use of Training Schools, Families, and Private Students. By Clara Weeks-Shaw. Third Edition, Thoroughly Revised and Enlarged. Cloth. Pp. 397. Price, $1.75. New York: D. Appleton & Co. 1902.

HOW TO SUCCEED IN THE PRACTICE OF MEDICINE. By Joseph McDowell Mathews, M.D., LL.D., President of American Medical Association, 1898-9. Cloth. Pp. 215. Price, $2.00. Louisville: John P. Morton & Co. 1902.

THE PHYSICIAN'S VISITING LIST. 1903. Fifty-second Year. Leather. Prices: Regular Edition, $1.00 to $2.25; Perpetual, $1.25 and $1.50; monthly, $0.75 to $1.00. Philadelphia: P. Blakiston's Son & Co.

THE A B C OF PHOTO-MICROGRAPHY. A Practical Handbook for Beginners. By W. H. Walmsley. Cloth. Pp. 155. Price, $1.25 net. With 29 Photo-Micrographs by the Author. New York: Tennant and Ward.

REGIONAL MINOR SURGERY. By George Gray Van Schaick, M.D., Attending Surgeon French Hospital, N. Y. Profusely Illustrated. Cloth. Pp. 226. Price, $1.50. New York: International Journal of Surgery Co.

LIFE AND CORRESPONDENCE OF HENRY INGERSOLL BOWDITCH. In Two Volumes. Vols. I and II. Cloth. Pp. 337 and 397 Respectively. Price, $5.00 net. Boston and New York: Houghton, Mifflin & Co. 1902.

THE PROCEEDINGS OF THE CHARAKA CLUB. Volume I, 8vo. Pp. 97. Price, $3.50 net. Printed for the Club by William R. Jenkins. New York: William Wood & Co. 1902. Limited Edition.

TRANSACTIONS OF THE MINNESOTA STATE MEDICAL SOCIETY. Thirty-third and Thirty-fourth Annual Meetings. 1901 and 1902. Cloth. Pp. 307. Minneapolis: Northwestern Lancet. 1902.

THIRTY-SECOND ANNUAL REPORT OF THE CENTRAL STATE HOSPITAL OF VIRGINIA, for the Fiscal Year Ending Sept. 30, 1902. Paper. Pp. 74. Richmond: Everett Waddey Co. 1902.

FORDWELL GRAHAM, or Lost and Won by the Hand of the Dead. By W. June Arlington. Cloth. Pp. 414. Price, $1.25. Philadelphia: Allen, Lane & Scott.

THE ISLE OF CONTENT, and Other Waifs of Thought. By George F. Butler, M.D. Cloth. Pp. 142. Price, $2.50. Concord, Mass.: The Erudite Press. 1902.

THIRTY-THIRD ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF MASSACHUSETTS. Cloth. Pp. 615. Boston: Wright & Potter Printing Co. 1902.

LUCE E SALUTE. FOTOTERAPIA-RADIOTERAPIA del Dott. Angelo Bellini, con 65 illustrazioni. Pp. 355. One Vol. Milano: Ulrico Hoepli.

The Public Service.

Army Changes.

Movements of Medical Officers, U. S. Army, under orders from the Adjutant-General's Office, Washington, D. C., from Dec. 15 to 20, 1902:

Hall, Henry M., contract surgeon, U. S. A., is granted leave of absence for one month.

O'Neill, Joseph A., contract surgeon, U. S. A., is granted leave of absence for one month.

Overton, David W., contract surgeon, U. S. A., is granted leave of absence to include Dec. 31, 1902.

Pinquard, Joseph, contract surgeon, U. S. A., is relieved from duty at Fort Leavenworth, Kan., to take effect on the arrival at that post of Captain John H. Stone, asst.-surgeon, U. S. A., and will then proceed to his home, Vinita, I. T., and on arrival report by letter to the Surgeon-General of the Army for annulment of contract.

Stockard, James K., contract surgeon, U. S. A., now at Greensboro, N. C., will proceed to Fort Delaware, Del., and report in person to the commanding officer of that post for duty and by letter to the commanding general, Department of the East.

The following named assistant surgeons, U. S. A., are relieved from duty at the places indicated after their respective names, and will report in person to the commanding general, Department of California, for transportation to the Philippine Islands on the transport to leave San Francisco Jan. 1, 1903, and on arrival at Manila will report in person to the commanding general, Division of the Philippines, for assignment to duty:

First Lieut. Milton E. Lando, discharge camp, Angel Island, Cal.; First Lieut. Charles Y. Brownlee, Bernicia Barracks, California.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending December 27:

Medical Inspector D. N. Bertolette, ordered to duty as fleet surgeon of the Pacific Station.

Medical Inspector E. H. Green, detached from duty as fleet surgeon, Pacific Station, and ordered to the *Wisconsin*.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Dec. 25, 1902:

Asst.-Surgeon H. B. Parker, granted leave of absence for 14 days from December 22.

Asst.-Surgeon M. J. White, granted leave of absence for 14 days from December 23.

Asst.-Surgeon B. J. Lloyd, relieved from duty at San Francisco Quarantine and directed to report to Surgeon A. H. Glennan, San Francisco, for duty.

A. A. Surgeon J. C. Ballard, granted leave of absence for five days from December 28.

A. A. Surgeon B. W. Goldsborough, leave of absence for three weeks granted by Department letter of Nov. 22, 1902, amended so that said leave shall be for 12 days only.

A. A. Surgeon S. C. Leonhardt, granted leave of absence for one month from January 1.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Dec. 27, 1902:

SMALLPOX—UNITED STATES.

California: Los Angeles, Dec. 7-14, 1 case; Sacramento, Dec. 6-13, 2 cases; San Francisco, Dec. 7-14, 3 cases.
Georgia: Atlanta, Dec. 10-17, 3 cases, 1 death.
Illinois: Chicago, Dec. 13-20, 2 cases.
Indiana: Elwood, Dec. 14-21, 1 case; Indianapolis, Dec. 13-20, 22 cases, 4 deaths.
Kentucky: Lexington, Dec. 13-20, 1 case.
Louisiana: New Orleans, Dec. 13-20, 1 case, imported from Monroe, La.
Massachusetts: Dec. 13-20, Boston, 16 cases, 6 deaths; Everett, 1 death; Lawrence, 2 cases.
Michigan: Grand Rapids, Dec. 13-20, 6 cases.
Missouri: St. Louis, Dec. 7-14, 14 cases.
Nebraska: Omaha, Dec. 13-20, 5 cases.
New Hampshire: Dec. 13-20, Manchester, 7 cases; Nashua, 15 cases.
New Jersey: Dec. 13-20, Camden, 3 cases; Newark, 2 cases.
New York: Dec. 13-20, Buffalo, 2 cases; New York, 1 case.
Ohio: Cincinnati, Dec. 12-19, 1 case; Cleveland, Dec. 13-20, 9 cases, 5 deaths; Dayton, Dec. 13-20, 7 cases; Hamilton, Dec. 13-20, 2 cases.
Pennsylvania: Dec. 13-20, Erie, 6 cases; Johnstown, 8 cases, 2 deaths; McKeesport, 1 case; Philadelphia, 15 cases.
South Carolina: Charleston, Dec. 6-13, 3 cases, 1 death.
Tennessee: Memphis, Dec. 6-13, 2 cases.
Washington: Tacoma, Dec. 7-14, 2 cases.
Wisconsin: Milwaukee, Dec. 6-20, 15 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Nov. 22-29, 9 cases, 1 death.
Belgium: Antwerp, Nov. 22-29, 1 case, 1 death.
Brazil: Bahia, Nov. 15-29, 4 cases, 1 death.
Ecuador: Guayaquil, Nov. 22-29, 2 deaths.
Gibraltar: Nov. 23-30, 1 case.
Great Britain: Birmingham, Nov. 29-Dec. 6, 1 case; Edinburgh, Nov. 29-Dec. 6, 1 case; Leeds, Nov. 29-Dec. 6, 3 cases, 1 death; Liverpool, Nov. 29-Dec. 6, 18 cases, 4 deaths; London, Nov. 22-Dec. 6, 10 cases.
India: Bombay, Nov. 11-25, 4 deaths; Calcutta, Nov. 15-22, 1 death; Madras, Nov. 8-15, 1 death.
Italy: Palermo, Nov. 22-29, 4 cases, 1 death.
Mexico: City of Mexico, Nov. 30-Dec. 7, 6 cases, 2 deaths.
Russia: Moscow, Nov. 15-22, 7 cases; Odessa, Nov. 22-29, 1 case; St. Petersburg, Nov. 22-29, 4 cases, 1 death.
Straits Settlements: Singapore, Oct. 8-25, 1 death.
Turkey: Constantinople, Nov. 23-30, 3 deaths.
Uruguay: Montevideo, Nov. 1-8, 16 cases, 1 death.

YELLOW FEVER.

Ecuador: Guayaquil, Nov. 29-Dec. 6, 4 cases.
Mexico: Dec. 6-13, Coatzacoalcos, 1 case; Tampico, 8 deaths; Vera Cruz, 13 cases, 4 deaths.

CHOLERA—INSULAR.

Philippines: Manila, Oct. 19-Nov. 1, 33 cases, 20 deaths; Cebu, Oct. 30, 1 death; Provinces, Oct. 19-Nov. 1, 7,764 cases, 4,806 deaths.

CHOLERA—FOREIGN.

Egypt: Alexandria, Nov. 22-29, 11 deaths.
India: Bombay, Dec. 11-25, 1 death; Calcutta, Nov. 15-22, 26 deaths.
Java: Batavia, Oct. 24-Nov. 8, 81 cases, 68 deaths.
Straits Settlements: Singapore, Oct. 18-25, 17 deaths.

PLAGUE.

China: Hongkong, Nov. 1-8, 1 case, 1 death.
India: Bombay, Nov. 11-25, 253 deaths; Calcutta, Nov. 15-22, 9 deaths; Karachi, Nov. 16-23, 19 cases, 18 deaths.

VOL. XL. CHICAGO, ILLINOIS, JANUARY 17, 1903. No. 3.

Address.

RECENT PROGRESS IN LARYNGOLOGY, OTOLOGY AND RHINOLOGY.

CHAIRMAN'S ADDRESS, DELIVERED BEFORE THE SECTION ON LARYNGOLOGY AND OTOLOGY, AT THE FIFTY-THIRD ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION, AT SARATOGA SPRINGS, N. Y., JUNE 10-13, 1902.

G. HUDSON MAKUEN, M.D.

PHILADELPHIA.

A NEW NAME SUGGESTED FOR THE SECTION.

We live in an age of specialism. No man, however ambitious, can any more hope to know all there is to know in medicine. The practitioner of to-day who would even approximate accuracy in his work, must perforce choose his specialty. Nor, indeed, is specialism a new thing, for, as Dr. Jonathan Wright of Brooklyn has pointed out in his recent interesting papers, there are evidences in literature of its having been practiced by the Egyptians more than fifteen hundred years before the Christian era. While these ancient writings contain no direct reference to laryngology and otology, it is interesting to note that Herodotus mentions "diseases of the head" among the specialities of Egyptian medicine. Thus may we not infer that the newest of our triad, rhinology, may be in fact the oldest and the first to be recognized as worthy of special practice. This being so, are we not somewhat neglectful of our sister specialty in denying her a place in the title of our Section. Making use, therefore, of one of the prerogatives of my position as your chairman, I would suggest that we adopt such measures as may be necessary to have our name changed so that it will read: The Section of Laryngology, Otology and Rhinology of the American Medical Association.

Whatever may have been the status of our specialty in ancient times it now ranks among the first of the specialties in medicine. While diseases of the throat, ear and nose have been recognized for centuries, it has remained for the modern laryngologist, otologist and rhinologist to develop a working classification of these diseases and a rational system of treatment. Indeed, laryngology, otology and rhinology, as we know and practice them to-day, may be said to have had their origin within the memory of us all. Their development and growth have been marvelously rapid and each succeeding year has witnessed important steps in advance. Other and abler men have written their early history, and it is of their more recent progress that I shall have the honor briefly to speak.

THE LARYNX AND ITS DISEASES.

Excellent work has been done in laryngology, although attention has been directed chiefly to the parts above the larynx. Dr. George Avellis of Frankfort-on-Main, who has made some investigations with reference to the singing organs of birds, claims that the larynges of the birds possessing beautiful voices do not differ widely from those not so gifted. He also claims that the laryngoscope reveals no peculiar conformation in the larynges of singers, and that the power to sing depends, not so much on the structure of the larynx as on the mental and intellectual bent of the individual.

Dr. Allen T. Haight, Chicago, describes a new aseptic throat mirror made from solid German silver highly polished and nickel plated. It has a universal handle made of steel and the connection is by ball and socket joint, to allow of easy adjustment to any position or angle. It may be sterilized by boiling.

Laryngectomy is no longer the unusual and dangerous operation it once was, and its results, largely perhaps on account of improved technic, are much more satisfactory, both to the patient and to the operator. Dr. D. Bryson Delavan and others are making some investigations relative to the value of the x-ray in the treatment of malignant tumors of the larynx. Tubercular laryngitis and its treatment still play a prominent part in the discussions of our meetings, and opinions are divided as to the frequency, and even the possibility, of primary tuberculosis of the larynx and as to the efficacy of radical surgical measures for its cure. Eruptions and ulcerations due to the use of orthoform have been reported by W. Dubreuilh.

Dr. S. Leduce of Nantes has invented a glass tube for the inspiration of remedial powers by which it is said the patient may make the necessary applications to his own throat.

DIPHTHERIA.

Antitoxin has added a new interest to the study of diphtheria. E. von Behring asserts in his book just published in Berlin that inasmuch as the Klebs-Löffler bacillus may be found in the throats of about 10 per cent. of the entire population it must in many cases either be of a non-virulent type or else some individuals are immune to its infection. The comparative immunity of physicians to the disease he ascribes to the unconscious auto-inoculation of the virus in small doses, and he suggests a more general immunity, and the final disappearance of the disease altogether, by the use of antitoxin inoculations. Should these views prove to be correct, the future treatment of diphtheria will consist largely in its prevention, not as at present by the isolation of those having been exposed to the disease, but by removing the natural predisposition to infection with antitoxin injections.

Dr. J. W. Steele, in some late statistics on the use of diphtheria antitoxin, has shown that the former death rate of 65 per cent. has been reduced to 16 per cent.,

and Dr. H. G. Jump reports excellent results from the inoculation of every child exposed to diphtheria with from 250 to 500 units of the antitoxin.

Some one has pointed out the fact that the virulence of the Klebs-Löffler bacillus is not a constant factor but has its periods of fluctuation, and that we may now be passing through a period in which the disease manifests itself in a mild form, and therefore antitoxin may not possess all the virtues that have been claimed for it. Of course, time alone can determine this point.

INTUBATION.

Dr. I. Dioniato, Turin, has introduced perforated intubation tubes in which he claims that the danger of sudden obstruction is almost entirely obviated by the circulation of the air through the perforations above the point of occlusion, and in 33 cases reported expulsion of the tube in only one case, whereas without perforation it occurred in about 18 per cent. of cases.

Dr. E. Collette of Anvers, Antwerp, reports the successful removal of intubation tubes with the electromagnet. The operation is easily performed, instantaneous and specially serviceable in cases of impending danger due to sudden obstruction of the tube.

Dr. Rudolph Matas of New Orleans has devised a graduated air pump for artificial respiration by direct laryngeal intubation with a modified O'Dwyer tube.

Dr. F. Kuhn of Leipsic has devised a flexible oral intubation tube which extends from the larynx out through the mouth. It is indicated during narcosis for operations on the upper air passages. It is said to prevent the aspiration of all secretions, and to make it possible to thoroughly pack the nasal and oral passages without interfering with the breathing. In cases of asphyxiation the air may be blown through the tube into the lungs.

ANESTHETICS.

Dr. H. P. Moser describes an apparatus for administering anesthetics, in operations on the respiratory tract, in which ether is forced through a tube by means of a bellows, the tube being held sufficiently far away from the mouth and nose of the patient to allow the operator to work unhampered by the administration and the patient is kept in a sitting posture.

Dr. William A. Briggs advises the mentholization of the mucosa of the air passages before, during and after etherization, and claims the following advantages: 1. Entire freedom from cough and the sense of impending suffocation, and comparative freedom from nausea, vomiting and retching. 2. The rapidity with which anesthesia may be induced and the ease and smoothness with which it may be maintained. 3. The entire absence or marked abbreviation of the period of excitement. 4. Economy both of ether and of time. 5. Profounder first anesthesia, under which minor operations may be done with more certainty. 6. Probably less post-operative nausea and vomiting.

Dr. George W. Crile has made some further investigations relative to the use of local applications of a weak solution of cocain and eucain in operations about the pharynx and larynx, and he claims that they prevent reflex respiratory inhibition, and that cardiac inhibition may be overcome by the hypodermic injections of atropin.

FOREIGN BODIES.

Dr. Roaldes has reported the results of special study of the technic of removing metallic foreign bodies from the air passages by means of a magnet. He is convinced that improvement of the technic would make it possible to remove such foreign bodies from the bronchus through the mouth by means of the combined use of a strong magnet and fluoroscopy and bronchoscopy.

Dr. A. Coolidge, Jr., Boston, speaks of the ease with which foreign bodies may be removed from the trachea and bronchi through a straight tube placed in a previously made tracheal opening, artificial light being reflected into the tube from a head mirror. This would seem to be a decided improvement over the old method of hunting blindly for such bodies. Dr. J. A. Killien reports the removal of a fishbone 22 mm. long from the left bronchus of a child three and a half years old, under control of the eye by means of bronchoscopy without injury to the tissues.

LOCAL ANESTHETICS.

Dr. Chas. A. Elsburg reports some cases illustrating the value of adrenalin chlorid, in the proportion of 1 to 5,000 to 1 to 20,000 solution, in conjunction with a sterile solution of eucain, cocain or Schleich's mixture for local anesthetics in minor surgical operations, to do away with the oozing of blood from the wound, and he claims that inasmuch as adrenalin is a cardiac stimulant it has the additional advantage of counteracting the depressing effect of either cocain or eucain, and it prevents congestion and pain after the anesthetic effects have worn off. A new local anesthetic, aconin, has been described before the French Academy of Medicine by Dr. Chauvel, and he claims that it is not toxic. Herter and Richards have shown that injections of adrenalin solution into the abdominal cavity of dogs has invariably produced well-marked glycosuria, and that 1 c.c. of adrenalin solution (1-1000 c.c. of water) applied to the surface of the pancreas was followed within ten minutes by the appearance of sugar in the urine.

WHOOPING COUGH AND ANGINA.

Dr. de Lamalleree reports remarkable results from the treatment of whooping cough with the inhalation of formic acid vapors.

Dr. William Cheatum, who has made a special study of the relation of angina to rheumatism, concludes that although the two diseases have many etiologic points in common their connection, although undoubted, is in many cases not yet clearly established.

Dr. Emil Mayer has been the first in this country to report a case of ulcerative angina in which was found the fusiform bacillus and the spirillum of Vincent. The difficulties and importance of making a differential diagnosis between this ulceration and chancre of the tonsil were clearly demonstrated.

THE TONSILS AND TONSILLOTOMY.

The function of the tonsil, and the indications for operative measures on the lymphadenoid tissue composing "Waldeyer's ring," still furnish a wide field for discussion. Opinions vary all the way from that of Bosworth, who stated some twenty years ago that practically there is no tonsil in the healthy throat, and who still is inclined to adhere to this view, to the opinion of those who claim that it is a normal physiologic structure with well-defined functions and that it should not be subjected to surgical interference except on evidences of the development of well-marked pathologic conditions. A careful review of the literature would seem to indicate that the latter is the more widely accepted view and that a wholesale removal of this tissue in the absence of any pathologic indications is not to be recommended.

That the complete removal of faucial tonsils may prove to be at least a temporary detriment to the voice has been shown in several cases coming under my own observation, and Dr. H. Lambert Lack of London claims that loss of the singing voice often follows the operation. I am convinced, however, that this is only a temporary loss due to the new condition in the pharynx, and that a little careful practice will always restore the voice and in those cases in which the operation has been well advised and skilfully executed there will be given to the voice additional beauty and power.

The various operations for the removal of the tonsil are beginning to be regarded with more and more trepidation on account of the danger of hemorrhage, both primary and secondary. Our present fear of accident is by no means a new thing, for the celebrated Italian surgeon, Fabricius, after describing the operation for tonsillotomy as performed by Celsus and Paulus Ægineta, says: "Wherefore we may gather that it is not entirely safe or easy to carry out the operation." "Consequently," to quote from Dr. Jonathan Wright, "he advises seizing the tonsil with a long forceps and drawing it out so that by skilfully making traction the tonsil as of its own accord will follow." Not many of us, I think, would be willing to submit our own throats to such a procedure or attempt to practice it on others. Damianos states that there are on record about 150 cases of severe hemorrhage following tonsillotomy, and that 7 of them proved fatal. He adds to the list another fatal case in which the incision passed through the plane of the outer capsule of the tonsil and divided the tonsillar arteries, which failed to contract or retract. He advises against the complete ablation of the tonsil on account of the danger from this source.

Dr. H. A. Leipziger also protests against regarding tonsillotomy as a minor operation, and thinks it should always be done in a well-appointed hospital, where ample opportunities exist for the control of hemorrhage. He is of the opinion that this accident is due to vasomotor influences which may be excluded by syncope or unconsciousness, and this he obtains by hypodermics of morphia. Secondary hemorrhages following tonsillotomy have also been reported by Drs. Homer M. Thomas, Henry Gradle, Otto T. Freer, W. L. Ballenger, N. H. Pierce, W. M. Casselberry, Lee Weber, Dunbar Roy and S. J. Knapp.

Dr. W. W. Keen, in reporting two cases of ligation of the external carotid artery for severe hemorrhage following slight operations in the pharynx and nose, takes occasion to emphasize the simplicity and effectiveness of the operation. It takes but a few minutes and it probably saved the lives of the two cases described. It would seem to follow that every throat and nose surgeon should be prepared to do this slight operation.

Dr. Crile has tried the experiment of temporarily clamping the carotid arteries in 19 dogs to prevent hemorrhage in operations about the head and neck. He also reports 18 clinical cases ranging in age from 7 months to 79 years in which this method was used with satisfactory results.

ADENOIDS.

The drift of opinion is more and more toward the early and complete removal of hypertrophied pharyngeal tonsils. Drs. E. J. Moure and Lafarelle, Bordeaux, France, have recorded the results of their examinations of 60 anatomic sections of the nasopharynx and the clinical study of 92 cases of adenoids, showing a great diversity in shape and size of this cavity and the impossibility of operating successfully in this region with instruments of fixed size and shape. They claim that digital examination should be made in all operative cases to ascertain whether the shape is, 1, arched; 2, contracted; 3, irregular with a recess; these being the varieties illustrated by cuts from actual preparations.

Dr. O. Stewart reports the removal of an adenoid mass measuring three-eighths of an inch in length by three-quarters of an inch in depth, from a child eleven days old, with immediate relief of the symptoms which were snoring and inability to nurse.

That there are still those who think that the removal of adenoids by operative measures is not necessary is indicated by the fact that Lapeyre reports the rapid disappearance of adenoid symptoms in twenty-eight cases by the internal administration of the tincture of iodin, in doses varying from 16 to 18 m. per day, in patients ranging from 5 to 9 years of age.

CLEFT PALATE.

Dr. G. V. I. Brown, in operating for cleft palate and harelip, advises approximation of the sides of the bony cleft by means of an apparatus for drawing the lateral halves of the superior maxillary bone toward each other and holding them there for some time prior to the operation for complete closure of the cleft. He also mentions a point to which your chairman has repeatedly referred, namely, that unless the operation is done early in the life of the patient the faculty of speech is not much improved, and that a complete change in the methods of articulation must be established by means of suitable mental and physical training.

W. Arbuthnot Lane, an English surgeon, recommends that the cleft be closed in the fourth or fifth week, and he mentions among the advantages of the early operation the fact that, the vessels being small, only a trifling amount of blood is lost, whereas in older persons the bleeding is often profuse. His method of operation when the cleft is large is to raise a flap of the mucous membrane and periosteum from one side and turning it over to suture it to the freshened margin of the other side, and he recommends the ligation of the palatine vessels to avoid hemorrhage.

Dr. George A. Raymond, a dental surgeon, asserts that the use of mechanical appliances is the best means for giving anything like perfect speech in cases of cleft palate, and this is probably true, unless the operation be done in the early weeks of childhood.

PARAFFIN INJECTIONS.

The saddle-back nose has received considerable attention during the year. Dr. F. W. Gwyer remedies this condition by means of a flap taken from the tip of the nose, and he renders the broadened alæ more shapely by removing a portion of the cartilage on either side. The operation that has attracted special attention, however, is the one devised by Gersuny. It consists in the subcutaneous injection of paraffin, and he has reported 40 cases successfully treated by this method. Broeckaert reports two successful cases of sunken nose greatly improved by Eckstein's method, which differs from that of Gersuny only in that the paraffin is of a higher melting point. He claims that the result is perfect, and that the operation will replace many of the tedious and delicate operations of plastic surgery. Dr. Scanes Spicer exhibited before the London Laryngological Society an interesting case successfully treated thus. Drs. Harmon Smith and F. J. Quinlan of New York City also report excellent results in many cases. Mr. R. Lake exhibited before the London Laryngological Society a case in which he injected paraffin into the inferior tur-

binate bodies for the relief of atrophic rhinitis, and the patient claimed to have experienced marked relief from all the symptoms.

Dr. John O. Roe has shown photographs of a patient kicked by a horse. The tip of the nose and the cartilaginous portion of the septum was torn away, and most excellent results were obtained by means of plastic surgery, using the inner portion of a thick upper lip.

Dr. John W. Murphy has exhibited some sections of a head previously hardened in a 3 per cent. solution of formaldehyd. The process of hardening continued over a period of three years, during which time the solution was changed every three months. Judging from the photographs of the plates the results were most satisfactory.

As a preliminary to intranasal operations Ostmann of Marbury recommends the obliteration of the blood vessels of the nose.

Dr. S. S. Bishop reports the removal of a rhinolith weighing seventy-one grains. On account of its great size he was obliged to take it away in sections after crushing it with powerful forceps. J. M. Ingersol of Cleveland reports the removal of a rhinolith weighing two drams. It was also removed in sections, and in one piece was found a bean which the patient recalled having put in his nose when a small boy about thirty years before.

Dr James Sawyer recommends a powdered desiccated suprarenal gland in the treatment of hay fever. Full pathologic effect has been obtained, and the drug is used for this purpose both locally and internally. Fink reports the apparent cure of eleven cases of hay fever by the insufflation of aristol into the maxillary antrum.

OPERATIONS ON THE SEPTUM AND TURBINATES.

Dr. Chas. H. Baker of Michigan reviews six so-called indications for the removal of the middle turbinal bone, and Chevalier Jackson regards the inferior turbinal of the concave side of the nostril as a frequent cause of deflection of the septum and recommends its removal at the time of operations of septal deflections. Dr. Walter J. Freeman has published an excellent thesis on the nasal septum.

Dr. Otto T. Freer describes the correction of septal deflections, after the manner of Krieg and Baenninghans, by the dissection of the deflected portion of the cartilage with no untoward results, such as tilting or falling in of the nose, and your speaker reports excellent results in the removal of the anterior two-thirds of the cartilaginous portion of the septum which was dislocated and projecting through the vestibule, presenting a somewhat unsightly appearance. Although a slight perforation was made in the mucous membrane of the opposite side during the dissection, it promptly healed and there is now scarcely any evidences of the operation. That this method will take the place of the Asch operation to any great extent is extremely doubtful. Dr. D. Braden Kyle has described some improvement on his own operation for correcting septal deflections by means of V-shaped incisions.

Flatau reports the cure of two cases of atrophic rhinitis by the implantation of a row of ivory pegs at the point of insertion of the inferior turbinated bone and that the operation under cocain was a very simple one.

Thomas H. Halsted of Syracuse, N. Y., reports a case of sudden blindness from empyema of the right maxillary and the ethmoidal and sphenoidal sinuses.

Not many of us will follow the example of Furet, who has gone through a healthy maxillary sinus for the purpose of trephining the sphenoidal sinuses. Bryan, Jansen and Luc have reported similar operations on the sphenoidal sinuses, but only when the maxillary sinus was also diseased. Furet claims that we are justified in doing this operation in all cases of sphenoidal sinusitis complicated with cerebral symptoms, and also in cases occurring of persons with narrow or malformed nasal fossæ.

THE ROENTGEN RAYS.

Mr. Lawrence of London reports a case of improvement of that rare condition, tubercular rhinitis, by the application of the Röntgen rays, a treatment which has proved to be of value in cases of lupus of the skin, and Mr. de Santi two cases of lupus of the interior of the nose, one treated by the Röntgen rays and the other by the internal administration of urea, ten grains to the ounce of water, combined with local curettage and lactic acid applications.

The *x*-ray has also been used by Dr. John H. Phillip to determine the location and size of the frontal sinuses, and the importance of this procedure is well illustrated by a case reported by Dr. Jonathan Wright, in which, the frontal sinus being absent, the frontal bone was perforated and the dura mater wounded with disastrous results. Dr. M. H. Cryer also speaks of a postmortem case in which the brain substance extended into the sinus and was partially removed before the nature of it was known. Drs. Chas. K. Mills and G. E. Pfahler reported some cases of clinical localization of brain tumors by the Röntgen rays.

Dr. Victor Alsen reports five cures of chronic empyema of the maxillary antrum by an operation through the canine fossa, which is intended to bring about a complete obliteration of the antrum by cicatricial tissue, and he claims that it is the only operation hitherto devised for the disease that can in any sense be called radical.

Dr. L. H. Pegler exhibited before the Laryngological Society of London a woman, aged 23, who was unable to breathe through her nose, although the passages were unobstructed, and who had a defective speech known as rhinolalia clausa. A large pad of adenoids and turbinal hypertrophies on both sides had been removed, leaving the nasal chambers entirely free, but after the operation the symptoms grew worse instead of better. It was regarded as a case of hysterical incoördination of the muscles of the soft palate and pharynx. A course of physical and mental training such as is used in hysterical aphonia would give, doubtless, the desired relief. Dr. Dundas Grant also reports a similar case, in which he considered the trouble to be due to anesthesia of the nasal mucous membrane. The patient could not feel the air and therefore thought she could breathe only through the mouth. This is probably the explanation of many cases of subjective obstruction.

DIAGNOSIS AND TREATMENT OF DEAFNESS.

Marage has invented an instrument for testing the hearing and massaging the drum membrane by means of the fundamental vibrations of the vowel sounds. As a therapeutic measure he claims for this practice marvelous results. Hearing was restored to normal in several cases of extreme deafness, and successful results in many cases of sclerotic otitis in which all other methods had failed. The special value of the procedure consists in the fact that the vibrations received by the ear drum approximate the normal vibrations of speech, and they serve the double purpose of massaging the ear drum and educating the auditory speech centers.

Dr. B. A. Randall emphasizes the value of binaural hearing, and thinks that because a person's ears may be engaged in hearing each a different thing from the other at one and the same time it is important that both should be kept in normal condition.

E. Amberg has invented an acumeter in which a steel ball of given weight falls on a metal plate. Great precision is claimed for the instrument, and examination of different patients by different physicians can be compared.

The use of the electric bougie for the dilation of strictures of the eustachian tube is still being held under judgment. While it may not have the wide application that some have claimed for it, and, like many good things, may be productive of great injury in unpracticed hands, it undoubtedly has its special indications.

Dr. F. R. Packard reports two cases of pus discharging from the parotid gland through the fissure of Santorini, the drum membrane being intact.

The importance of examining the ears in every case of severe acute pneumonia in children is pointed out by T. Stacey Bilson, who believes that otitis media is present in the majority of fatal cases of this disease.

Dr. M. G. Ward claims good results from the use of formalin in suppurations of the middle ear, and states that many of the disagreeable symptoms, such as fetid odor, discharge, etc., are promptly relieved.

Dr. H. Gaudier recommends the instillation of methylene blue in otitis media and fetid otorrhea of children. Dr. A. Ghon gives evidence to prove that the *Micrococcus catarrhalis* is pathogenic and that it closely resembles the pneumococcus and the influenza bacillus.

For more than a year Dr. E.P. Snydacker of Chicago has used the microscope as an aid to the diagnosis and prognosis of chronic suppuration of the middle ear, and he thinks that bacteriologic examinations of middle ear discharges have no value whatever in determining the outcome of the disease.

Dr. Chalmers Watson uses a preparation of bone marrow, which he calls myelocene, in the treatment of deafness from middle ear origin. He claims that this product produces an internal secretion which acts as a powerful prophylactic against the action of bacteria.

THE MASTOID.

The indications for surgical intervention in mastoid disease are not yet well defined, for the symptoms bear no distinct relation to the pathologic conditions within the mastoid process. Auscultation of the mastoid by means of a stethoscope and tuning fork is strongly recommended as being of a diagnostic value.

Dr. G. Alexander reports eleven cases of mastoid operation in Politzer's clinic, under cocain anesthesia, and so successful was the procedure that he recommends the method in all cases where the coöperation of the patient can be secured.

Dr. C. A. Ballence reports a case in which a ragged opening in the dura one-third of an inch in diameter, through which the brain was visible, and a clear fluid escaped, was successfully closed by a graft of epithelium. Skin grafting after mastoid operations has come to be an important feature of aural surgery.

ILLUSTRATIVE CASES OF CEREBROSPINAL FEVER.*

J. P. CROZER GRIFFITH, M.D.
Clinical Professor of Children's Diseases in the University of Pennsylvania.
PHILADELPHIA.

The tendency of infectious diseases to exhibit themselves in certain well-differentiated forms or types is perhaps particularly well seen in cerebrospinal fever. So true is this that although the complex of symptoms is exceedingly characteristic in the cases of average severity, the variations on the one hand to the malignant form, or, on the other, to the extremely mild or the abortive type are so great that the diagnosis may be rendered very difficult.

The title "Cerebrospinal Fever" has been chosen advisedly instead of cerebrospinal meningitis, because I have in mind here the disease which appears to be a specific infectious one, coming generally in epidemics, and having a certain definite though varying group of symptoms. It is by no means certain that this affection differs in any way from cerebrospinal meningitis not of an epidemic nature. From this latter point of view the cases are, of course, very much more numerous and the symptoms still more varying. All of the cases used in this paper with the exception of the last are, however, instances of the epidemic form of the disease, and in the last one the symptoms are so typical of one of the forms that I have used it for the sake of illustration.

Just a short sketch of the ordinary symptoms of the affection may not be out of place. The disease is not a very common one in this country as compared with some of the other infectious disorders. Its symptoms vary greatly in different epidemics and in different cases in the same epidemic. To follow one of the simpler methods of subdivision we may divide the cases into the following types: (1) the ordinary, (2) the malignant, (3) the mild, (4) the abortive, (5) the intermittent, (6) the chronic.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. Edwin Rosenthal, H. M. McClanahan and Samuel W. Kelley.

1. In the ordinary form prodromes may be present, but are usually absent. When present they last a few hours up to a few days and are very indefinite in nature. The attack begins with headache, vomiting, fever, and in adults a chill. Children often have convulsions. The face has an expression of pain. Very soon stiffness and pain in the neck and back develop. This is very characteristic. Headache, photophobia, irritability and other evidences of meningitis are marked. The forearms are flexed on the arms, and the legs on the thighs, the head is often very much retracted, there is intense pain and decided general hyperesthesia. Delirium is common, the bowels are constipated, the abdomen often retracted, herpes is frequently seen and petechiæ often develop. Convalescence may begin in one or two weeks, but is often deferred much later.

2. In the malignant form the disease begins with extreme suddenness and the symptoms appear at once and in the most intense way. Collapse with coma soon develops. General convulsions are common. Death occurs in a few hours.

3. In the mild form the patient may be so little ill that he hardly needs to go to bed. There is severe headache, possibly nausea, rarely vomiting and but little or no fever. The neck may be slightly stiff. The diagnosis is almost impossible in sporadic cases.

4. In the abortive form the disease begins as in the ordinary type, but recovery suddenly takes place in two or three days.

5. The intermittent form exhibits intermissions in the symptoms which suggest malarial fever, but which do not occur with any definite regularity.

6. In the chronic form the case drags on for weeks. There is vomiting, irregular fever, sometimes temporary improvement followed by disappointing relapses and progressive and extreme emaciation. I have never seen greater wasting than may take place in this condition.

With the purpose of emphasizing the variation in the symptoms which this disease may show rather than with the thought of advancing anything new on the subject, it has seemed to me of possible interest to present to you the following histories of three different family epidemics or outbreaks of the affection, and of two chronic cases, one of which occurred sporadically. Though I have seen many other instances of the disease I will make no reference to them, as they illustrate no special point.

The first of the epidemics which I shall record occurred in two sisters whose parents fled with them from the board of health of one of the towns of Pennsylvania to Philadelphia. They entered the Children's Hospital and were found here by the local health authorities, but were allowed to remain with us. Their clinical histories are as follows:

Case 1.—Minnie W., 4 years, 4 months of age; admitted to the Children's Hospital, Philadelphia, May 2, 1893. She was one of three children, the youngest a baby of 1½ years, and the other entering the hospital at the same time as herself. Though weakly at first she became a strong child and had never had any serious illness until the present one. She was not at all well on the night of April 30. Awaking on the morning of May 1 she refused to eat, was thirsty and vomited. The vomiting continued throughout the day. The child lay on the lounge, constantly calling for water, was restless and dull, but recognized her parents. The bowels were moved twice on the night of May 1. On May 2 the thirst was still intense, although vomiting occurred every time that water was taken.

Examination on admission showed the child extremely restless and throwing herself about the bed. The mind was evidently not clear, the head was somewhat retracted, the tongue coated, the pupils dilated and not responding to light. Small purpuric spots about the size of a pinhead were scattered over the trunk, especially over the abdomen.

During the day restlessness continued. There was some cyanosis and the pulse was weak. Bromid of potash given by the mouth was vomited. By afternoon stiffness and retraction of the neck had increased decidedly; there was gritting of the teeth; the *tâche meningitique* was not well marked.

The child continued in much the same condition for about twelve days, with the mental state slightly improving. The head was then only slightly retracted, and the mind seemed for the most part clear, the pupils having been normal for several days. She slept much, though lightly, and she had been able for some days to lie upon the back. She continued to lie quietly most of the time, though sometimes fretful, with no retraction of the neck during most of the month of May. There was no stiffness of the neck. On June 1, i. e., about the thirtieth day of the disease, it was noticed that she was still irritable. On June 27, nearly two months from the onset, a note was made that she was, on the whole, steadily improving, talked to her father, tried to sit up, and fed herself, although still very weak.

The temperature had been elevated at first, reaching frequently 104, and then gradually falling, finally showing well-marked morning remission with evening rise. It did not remain continuously normal until about May 27, a period of twenty-five days from the date of admission.

The child was taken home shortly after the end of June, and some months later was brought back to the hospital on account of absolute deafness, which the aural surgeon reported to be due to the cerebrospinal fever.

Case 2.—Rose W., 3 years, 4 months; admitted to the Children's Hospital the same day as her sister—May 2, 1893.

She had always been well except for measles a year before and an attack of vomiting three months ago. She was taken ill with the present attack April 27, with pain in her foot. Swelling of the face then developed, but soon disappeared. Very soon after this the neck became stiff and the head retracted. On the first and second night of the disease she was extremely restless with constant jactitation. After that she was stuporous, calling for water at times, crying out when disturbed as though in pain, with opisthotonos, marked cyanosis, and small reddish spots on the trunk.

Examination on admission, the fifth day of the disease, showed the child stuporous, occasionally crying for water, and not putting out the tongue when requested. The head was much retracted, the pupils dilated and not responsive to light. The reddish spots mentioned were found on the back and chest. By afternoon there was a very marked arching of the back and retraction of the head. Efforts to straighten the body gave pain. The spots were not so numerous as on admission. They disappeared on pressure. The *tâche meningitique* was slightly marked on the abdomen. For over a week from this date the mental state improved somewhat and the retraction of the head seemed disappearing. By May 12, two weeks from the onset, the child was talking, and interesting herself with objects given her. By this time there was little retraction of the head, although passive movement of it caused pain. She had been excessively irritable for a time, but this had now nearly disappeared. The expression of the face was entirely intelligent. After this date up to the end of the first month she was not so well. The retraction of the head and the irritability had returned. Removal to the general ward had been followed by an increase of symptoms, and she was again put in a separate room. By May 22, the twenty-fifth day of the disease, she was comatose, with extreme opisthotonos, resting on her head and nates. By May 29 this was slightly better, but she lay entirely quiet, unconscious, with dilated pupils, staring eyes and frequent twitching of the eyeballs. The *tâche* on the abdomen was now very marked. From this time on she grew steadily worse. Emaciation was decided. Sensation to pin-prick seemed entirely absent. On June 27, two months after the onset, a note was made that she had continued lying almost like a log, with forearms extremely pronated, wrists flexed at a right angle, feet in extreme extension, ankles, elbows and wrists stiff, fingers and

thumbs flexed, pulse weak, swallowing difficult. Ecchymotic and purpuric spots, most of them minute, were scattered over the trunk and to some extent on the legs and arms. This condition continued until July 11, two and a half months from the beginning of the affection, the body becoming covered with a widespread purpuric eruption. Unconsciousness persisted, the child lying like a log. She died on this date.

These cases illustrate a grave form of the disease; the first recovering after a long illness and showing one of the sequels, absolute deafness, which is not an infrequent result in this affection. Both cases were treated with occasional doses of bromids and with the persistent administration of opium in fairly large amount. The second case illustrates very well the extreme opisthotonos which may develop, the head at times almost touching the back between the shoulders. It showed also the widespread purpuric eruption which sometimes occurs in this disease, and the temporary improvement followed by relapse, which unfortunately is not an uncommon occurrence.

The second epidemic was most interesting, showing three types of the disease: the malignant, the one of average severity and the very mild. All three were members of one family, two of them being admitted to the Children's Hospital on the same day.

CASE 3.—Charles K., 2 years old; admitted to Children's Hospital on Feb. 23, 1900. The child was taken ill the day before with symptoms not well defined or described. He was brought to the hospital on account of convulsions. There had been no irregularity of the bowels. On admission he was in violent convulsions, with a temperature of 101 degrees, which rose to 103 by 4 p. m., when he died, the convulsions having continued unabated.

CASE 4.—Joe K., 4 years old; admitted to the Children's Hospital on Feb. 23, 1900. He was taken ill February 15 with fever. The bowels had been regular. On admission, i. e., the ninth day of the disease, he was found to be unconscious, arousing slightly when disturbed. There was occasional gritting of the teeth. The pupils reacted to light, the face was pale, the neck stiff, the heart, lungs and abdominal viscera normal; a well-marked *tâche meningitique* was present; the knees were constantly drawn up; Kernig's sign was absent. During the night he was very restless, crying out almost continuously. On the morning of the 24th his pulse was somewhat weaker; there was twitching of the muscles of the face; the neck was very rigid. The child was extremely delirious and restless, either throwing himself about and climbing up in the bed, or lying on his side with his legs drawn up. The neck was only slightly retracted. He realized when milk was offered to him and drank it. On February 25 lumbar puncture was performed, but no fluid was obtained. By the 28th he was quieter and was more disposed to lie on the back. By March 1, i. e., two weeks from the onset, the legs were at times extended, and he was clearly much better in every way. On the next day he was able to take a glass of milk in his own hands. The *tâche* was still present, although the neck was not so rigid. No eruption had been present at any time. His mind was distinctly clear and the general condition better. From this time on the condition continued to improve until March 9, the end of the third week, when the temperature rose and the throat became red and the nose was discharging. By the end of the fifth week he was very much wasted, the neck was still rigid, a slight *tâche* was present, there was no pain except on moving. The child would smile feebly and put out his hands when approached, but looked weak and ill. From this time on he failed to improve. His neck remained slightly rigid, his appetite diminished, he cried if disturbed. His legs were again drawn up and could not be extended without pain, and the mind again commenced to be clouded, and by April 12, the end of the eighth week, he was unconscious. He again improved somewhat, and was removed by his parents. His after-history is unknown to us.

The temperature of this child was high on admission to the hospital and continued irregularly so until nearly the ninth of March, when, contemporaneously with the general improvement, it was on some days below 100. On the 12th it rose again to 104 or 105 and from this date onward showed great irregularities, reaching sometimes almost normal and sometimes 105. When the child was removed from the hospital it showed still the same irregularity.

CASE 5.—Mary K., 5 years old; admitted to Children's Hospital, Feb. 23, 1900, on the same day as her two brothers. Her previous history and the day of the onset of the disease are not recorded, but she was sent to us with the diagnosis of typhoid fever, and it is therefore probable that she had been ill for some days. On admission she was pale, lay quietly, or cried when disturbed. Her neck was rigid, the pupils reacted to light and were not dilated, the heart and lungs were normal, and the *tâche meningitique* was present on the abdomen. She slept much on this day and on the next. When aroused she was conscious and had an intelligent expression, and protruded the tongue when requested. The head was not retracted, and the legs were extended, although the neck was stiff. When lying on her side the back was slightly hollowed. By February 25 her intelligence seemed entirely good. The child lay comfortably on her back. Her neck was still stiff and passive movement of the head gave pain. On this date lumbar puncture was performed, but no fluid was obtained. On the 28th she had very greatly improved, and seemed to understand all signs made to her (she did not speak English), and her neck was no longer stiff. By March 3 she was entirely convalescent, and by the 10th was out of bed.

Her temperature ranged between 101 and 105 during the early days of her presence in the hospital. From February 26 to March 2 it was about 100, with only slight variation, and after this latter date was practically normal.

This epidemic illustrates, as stated, three types of the disease. In Case 3 the diagnosis could not possibly have been made had it not been for the family history. The course toward the fatal issue was rapid in the extreme. Case 4 illustrates one of the more chronic forms, yet differing from that of the case of recovery of the first epidemic (Case 1). There were never so marked cerebrospinal symptoms, but, as sometimes seen in this disease, the child seemed unable to progress, and the tendency to relapse was very evident. The third case was of so mild a type that a diagnosis could not have been made had it been an isolated instance. The rigidity of the neck was so trifling that it might easily have been overlooked. The child had not at any time seemed particularly ill.

The third epidemic illustrates another very interesting fact, namely, the relationship which this disease, cerebrospinal fever, bears to pneumonia. As is well known, the germ of the two diseases is very probably the same. The cases were seen in consultation with Dr. James C. Chestnut of Philadelphia.

CASE 6.—Frank B., 6 years old; seen for the first time Nov. 18, 1900. The child had been taken ill November 15 with headache, vomiting, high fever and slight cough. On examination nothing was discovered wrong with the respiratory apparatus. On the next day, the 19th, the child still had fever and was very restless and constantly delirious. Severe pain in the back of the neck was occasioned by any movement of the head. There was no *tâche*. On the 20th he was rather dull, delirious, seemed to dread the light, and continued to suffer from the pain in the back of the neck, and to cry out whenever the head was moved. At times there was arching of the body or jactitation. Respiration was rather rapid but easy, fever continued, examination of the lungs showed no positive changes. By November 21, i. e., after six days of illness, he was worse in every way, and the temperature was still high. On the next day he was noticed to be excessively restless nearly all the time, with continued unconsciousness, dilated pupils, high fever, occasional flushing of the skin, well-marked *tâche meningitique*, irregular and often slow pulse, and pain on passive movements of the neck. A blood count on this date gave 32,000 leucocytes.

From this time the child failed rapidly. The tongue grew dry, and inability to swallow developed. Attacks of sinking occurred and the temperature fell to about 102. Examination for Kernig's sign on November 25, the child lying on its back, gave a negative result. Death occurred November 26, after a week and a half of illness. No autopsy was permitted, and even a postmortem lumbar puncture was refused.

CASE 7.—Samuel B., 10 years; seen for the first time Nov. 20, 1900. The child was taken ill suddenly on November 19, four days after the onset of sickness in his brother Frank—with fever, vomiting, headache and restlessness. Examination showed him to be dull, sleepy and not responsive to questions or to the request to put out his tongue. He was irritable, resisted examination, and lay curled up on his side. On the 21st he was rather better, but still had fever. On the 22d his mind was clear; the temperature was still elevated; the *tâche* was present on the abdomen; there was no pain complained of; suspicious physical signs pointing to pneumonia of the right lung were discovered. On November 23, the fifth day of the disease, the temperature fell critically to normal; the *tâche* was still present and the right lung was found extensively consolidated. By the 28th the lung had apparently undergone resolution entirely and the child was quite convalescent.

CASE 8.—Clifford B., 4 years old; seen for the first time on Nov. 18, 1900. He was taken ill about November 11, four days before his brother Frank, with fever and cough. These symptoms had continued with some acceleration of respiration and slight delirium on waking from sleep. Examination showed consolidation of the left lung posteriorly. The abdomen was slightly distended; the liver and spleen normal in size. By November 20, the tenth day of the disease, the child was better in general condition, but the consolidation of the lung had extended. The *tâche* on the abdomen was marked. The child had had no nervous symptoms and his mind was entirely clear throughout. By November 22 the temperature had fallen to normal and the child was convalescing.

Here we have three children taken ill within a week of each other. The first to be affected (Case 8) suffered almost purely from croupous pneumonia, the only symptom suggesting meningitis being a *tâche cerebrale,* which was unusually well marked. Yet this was not, of course, positive proof that meningitis was actually present.

The last child to be taken ill (Case 7) exhibited a condition which could hardly be considered merely symptomatic of pneumonia. It suggested rather a cerebrospinal fever of mild type, such as the third case of the second epidemic (Case 5) exhibited, combined with an involvement of the lung. The remaining child (Case 6) gave a typical picture of severe meningitis with no involvement of the lung discoverable. It is greatly to be regretted that lumbar puncture was not permitted in these cases. Yet even in the absence of positive proof scarcely any other conclusion is justifiable than that all three children were attacked by the same infectious agent, which showed merely a difference in the point elected for its specially deleterious action.

The next case, although isolated, is clearly traceable to a known infection. It was seen in consultation with Dr. George B. Wood of Philadelphia.

CASE 9.—Roscoe L., male, 10 years old, was exposed some time during the autumn of 1898 to cerebrospinal fever while his father was in camp at Tampa, where several cases of the disease were known to exist. The exact details of the case are not known, since a record was not kept, but are about as follows:

The boy came to Philadelphia and about two weeks later developed the first symptoms of the disease and the diagnosis of cerebrospinal fever was made. The case ran a characteristically chronic course for about two months. At times the disease strongly suggested malarial fever, but close observation of the temperature showed an absence of regularity. There was a decided tendency, on the whole, for the temperature to resemble a septic fever, being elevated in the evening and depressed in the morning. With the elevation of temperature the mental state and the general nervous symptoms always became worse, the child being delirious and exceedingly irritable. Apart from these changes there repeatedly occurred periods where convalescence seemed established. In these the temperature remained practically normal, the mind quite clear, and the nervous symptoms absent. Then relapses would occur with fever, retraction of the head, vomiting, rigidity of the spin, and intense pain in the neck. As the disease progressed emaciation became appalling. Towards the end he complained of not being able to see distinctly, although hearing was still good. Vomiting finally became a very pronounced symptom and no food could be retained. He died, practically from starvation, after an illness of about two months.

This case illustrates especially well the repeated disappointing relapses which take place in some of the chronic forms, and the emaciation which may finally result. The boy was as wasted as the most marantic infant I have ever seen.

The last case was for a time a most puzzling one in the matter of diagnosis.

CASE 10.—Charlie W., 6 years old; admitted to the University Hospital on Aug. 9, 1901. Without previous symptoms he was noticed to be slightly dull on the morning of August 5, to refuse his food, and to complain of abdominal pain. The symptoms continued, and on admission to the hospital on the fifth day of the disease he was in a heavy stuporous state, not answering when spoken to, crying when disturbed, with the neck slightly rigid, and the respiration quiet. Examination of the blood showed a leucocytosis of 35,000 and a positive Widal reaction. The urine contained a trace of albumin. The temperature was over 105 F. This condition continued with very little change, with irritability and stupor alternating. The temperature remained elevated except when reduced by tub-baths. There were sometimes drops to 99 F., or thereabouts, without the agency of a bath, but this did not happen often. The child was frequently very nervous, and would cry out when touched. The *tâche meningitique* was present on the abdomen, and there was some photophobia. The leucocyte count reached as high as 43,620 to the cm. on August 11.

Examination on September 7, after a month's illness, showed the absence of any affection of the heart or lungs, and of discharge from the ears. The pupils reacted to light, there was partial paralysis of the muscles of the right side of the tongue and tenderness over the entire spinal column, although most marked in the cervical region. The *tâche meningitique* developed slowly. Babinski's reflex could not be obtained.

The repeated examination of the blood had shown always a high leucocyte count, never below 35,000. The temperature had grown gradually more irregular, and after August 27 hydrotherapy was no longer needed.

The child now improved, although almost imperceptibly. The temperature continued extremely irregular and generally considerably elevated. He was for the most part unconscious, but cried when disturbed. Sometimes he was very restless and fretful at night time. He took his nourishment fairly well. The leucocyte count on September 26 was 22,120. By this time the child was distinctly improving, being decidedly brighter, less fretful by day and sleeping more by night. By October 3, about two months from the onset of the attack, his temperature was often below 100, though occasionally slightly more elevated, and was seldom over 102. He complained frequently of headache and of pain in the abdomen. He seemed to understand everything that was said to him. A few days later the Widal reaction was for a second time positive. Now that he could protrude his tongue when asked to do so, it was noticed that the right side was very greatly atrophied, the left side being normal and the tip being turned to the right. He had great difficulty in masticating and even in swallowing soft food.

He was very tremulous and there was some pain in the neck in passive movement of the head. By November, after an illness of three months, he was still quite sick, although the mental condition was improved. The temperature was now generally below 100, although there were occasional rises to 103 or 104, for which there appeared to be no reason. The bowels, which for a long time had been opened once or twice a day, now be-

came less frequently moved. Early in December, i. e., after four months' illness, he commenced to sit up part of every day and was bright, frequently talking and singing. The condition of the tongue was unchanged. It was not until the early part of January, after five months of illness, that he was able to stand alone, although he was still unable to walk. During his illness he had grown very thin though not extremely emaciated. He was discharged from the hospital at the end of January, about five and three-quarter months from the time of the beginning of the attack. By that time he was apparently nearly well, although still thin and not strong, and still with occasional rises of temperature to between 100 and 101. The number of leucocytes by this time had fallen to 16,800 and the Widal reaction was negative.

The interesting feature of this last case is, as stated, the question of diagnosis. The Widal reaction and the high leucocyte count exactly contradicted each other. It was at first supposed that the child had typhoid fever with possibly some local inflammatory process which accounted for the increased number of white cells. As the case progressed, however, the diagnosis of cerebrospinal fever became more certain, and the remarkable hemiatrophy of the tongue seemed to assure it. From this point of view the Widal reaction must then either have been the result of typhoid fever which had occurred at some previous time in the child's life and had never been recognized, or of an attack of this disease occurring coincident with the cerebrospinal fever. Which of these two suppositions is the most probable can only be surmised.

DISCUSSION.

DR. J. V. KOFRON, Cleveland, Ohio—I should like to ask if Dr. Griffith searched for Kernig's sign, and how much reliance he places on it.

DR. C. F. WAHRER, Fort Madison, Iowa—I had a case in a girl of 3½ years, which had been treated by an intelligent country physician for typhoid fever. As we all know, the symptoms in these two diseases are not always very clear. The child was stupid and had a temperature reaching as high as 106 F., and remaining most of the time at about 102 F., without abdominal tenderness. There had been a slight rash, which had been mistaken for typhoid fever. At the end of two weeks I was asked to see the patient with the physician. From the spinal rigidity and from the application of Kernig's sign, as well as from the general symptomatology, I felt justified in changing the diagnosis to cerebrospinal fever. The subsequent history proved the correctness of this diagnosis. At times there was violent opisthotonos and severe spasmodic contractions were also present, with emaciation to a remarkable degree. While many times the patient seemed to be conscious, she was unable apparently to receive an impression or give one. At times this patient seemed better and at other times worse. I saw the child once or twice afterward and believed she would ultimately recover on account of having held out so well. For ten weeks the disease lasted, the child finally succumbing with symptoms such as have been described in this paper. Would a Widal's test for typhoid and the microscopic test of spinal fluid for the Weichselbaum's bacillus always determine this differential diagnosis?

DR. I. A. ABT, Chicago—What should be done with regard to the isolation of these cases? Should they be treated in the general wards of hospitals? I have seen them treated in the wards and in homes without any attempt at isolation. The experience of Dr. Griffith with this disease, especially as to its epidemic nature, should, I think, lead us to isolate them. The deafness which follows attacks of cerebrospinal meningitis has received attention. It has been shown in connection with a study of the subject of deaf mutism that this condition increases in those years in which cerebrospinal meningitis is epidemic in certain sections of the country. I have in mind a case of cerebrospinal meningitis occurring in a child of 2½ years. The duration of the disease was protracted, and lumbar puncture showed the presence of the *Diplococcus intracellularis*. The child eventually recovered with a marked hydrocephalus. This occurred five or six years ago, and I occasionally see the child now, and find that the hydrocephalus is on the increase. Recently I reported 90 cases of typhoid, which I studied in my hospital practice, and two of these very closely simulated cerebrospinal meningitis. One of them was looked on as an example of cerebrospinal meningitis for a period of one week after admission. The child entered the hospital with severe headache, vomiting and high temperature; opisthotonos was present as well as marked delirium. A lumbar puncture was made and the Widal test at the same time. The former was positive, while the latter gave no growth on the smears. The meningeal symptoms, however, were so marked that we were inclined to regard it as a case of meningitis. At the end of a week the meningeal symptoms subsided, and the typhoid symptoms became more prominent. I know that these cases of meningismus are common enough, nevertheless, when one has such a case under examination for an entire week, wondering whether the Widal test or the results of lumbar puncture will clear up the diagnosis, it seems worth while to emphasize the fact that meningeal symptoms persisting and striking in character may occur in several acute infectious diseases.

DR. T. M. ROTCH, Boston—This is an exceedingly interesting class of cases. In private practice it becomes a very serious matter at times what to tell the parents as to the diagnosis and prognosis. In hospital practice it is not of so much importance. I have had a number of these cases to treat, both in hospital and private practice, in Boston during the last two or three years. The first thing that is asked is concerning the diagnosis, and that is a difficult question to answer. The physical signs of cerebrospinal meningitis in the earlier periods of life are very indefinite at times. One does not get marked symptoms, just as one does not observe in babies marked signs in cases of tubercular meningitis. Nevertheless, we must make a diagnosis. These cases may occur in very young infants without any rigidity of the neck, opisthotonos or any special sensitiveness to touch. I have had a case in a baby three or four days old, in which there was nothing but slight irregular convulsions, and in which lumbar puncture proved conclusively, by the presence of the *Diplococcus intracellularis*, the importance of the case. Lumbar puncture is of great value for diagnostic purposes. Moreover, it is in the very early days—in fact, in the first week almost—that we must use lumbar puncture in order to get positive results. This diplococcus, unlike the bacillus of typhoid, passes away very quickly, so that if lumbar puncture is delayed its results are untrustworthy. This applies even to pronounced cases of cerebrospinal meningitis. In like manner the Widal reaction may show the presence of typhoid, but we do not know at what time, as in the case reported by Dr. Griffith. The Widal reaction lasts for months, and perhaps for a year, after an attack of typhoid. If there is a Widal reaction and a clear fluid following lumbar puncture, without evidence of meningitis, one may be pretty sure that there is a typhoid fever with only the symptoms of meningitis arising from the toxins of typhoid. Typhoid fever, being a benign disease, in the early months and years of life children will get well; on the other hand, cerebrospinal meningitis is an exceedingly dangerous disease. Lumbar puncture has so far not seemed to be curative in cases of meningitis, though most useful in diagnosis. I had a case in my wards last winter which had passed through the acute stages and become chronic. The child was practically idiotic and was failing. I had another lumbar puncture made, simply to see whether the condition could be relieved. There was no question that after the withdrawal of the fluid the child became brighter, and it eventually recovered. One case does not prove anything, but it is interesting, and I may say that I am about to advise this procedure in another case now under observation. I should advise practitioners generally to make use of this procedure more freely in these exceedingly severe and desperate cases. In the cases of stupor and progressive idiocy the lumbar puncture is especially useful. The fluid should be allowed to flow as long as it will drain freely. I do not aspirate it, but allow it to flow under its own pressure. Sometimes only a dram or two are removed; at other times much more escapes. The Widal reaction is very apt not to be found

in the first two weeks of typhoid fever in a child, but when found is positive. Lumbar puncture will also show whether or not there is a typhoidal meningitis. Meningeal symptoms are common in typhoid without meningitis, but there is also a true meningitis caused by the typhoid bacillus. These cases may show all sorts of disorganization of the brain or cord, which may be attributed to cerebrospinal meningitis, but which are really due to the typhoid meningitis.

The fulminating cases are certainly the most dangerous. Usually the favorable cases are those which linger until the second or third week. If the disease lasts longer than this, however, the parents should be warned that the prognosis is more grave. Having passed into the third or fourth week the parents should be told that the child will not die of the acute process, but that the disease has become chronic. Unfortunately, these cases are becoming more and more common, and, as a rule, the prognosis is bad. In Henoch's cases in Berlin, some fifteen years ago, recovery took place. My cases of about ten years ago all died, while within the last few years a certain number of the chronic variety have recovered. Statistics of this kind may, in time, enable us to make a fairly correct prognosis as the disease progresses. The chronic cases are very interesting. At times they go on until the child gets extremely emaciated. Not only this, but rigidity and contractures occur and the child becomes idiotic. Sometimes, however, all these symptoms pass off. I know of such a case in Boston, in which the disease lasted for months and was associated with great mental disturbance, and yet to-day this person is a very bright and intelligent man. We should, therefore, be cautious in giving the prognosis. There is a much better opportunity for recovery than in any other form of chronic central nervous disease. I have now under observation a young baby of twelve months, on whom I intend to resort to lumbar puncture. The case has lasted for three or four months; the child is dull and practically idiotic. These cases of chronic meningitis, as you know, run on with a temperature of 101, 102 or 103 F. for a week, and then the temperature will run for four or five days or more nearly normal, the child meanwhile improving. This will be followed, however, by another relapse. The child I have spoken of has had seven relapses, and, of course, each relapse adds so much more to the danger. It comes finally to a question of nourishment. This baby vomited everything it took after the third or fourth relapse. I then advised the physician to feed it with a tube, and it is now three months that the child has been fed every three hours with three or four ounces of milk introduced into the stomach by means of a stomach tube. The child had lost the power of swallowing, or at least regurgitated everything swallowed in the usual way, but this has not occurred since the food has been introduced by the tube.

To summarize: It is not unusual to find cases in which the diagnosis of cerebrospinal meningitis is not very evident; hence lumbar puncture is useful. Again, tell the parents that the first four or five days are very dangerous, and that another dangerous period comes in the second or third week, the danger then being not so much as regards the sacrifice of life as of the disease becoming chronic and the mental faculties greatly impaired. Lastly, we must keep up the nutrition by every possible means.

Dr. Edwin Rosenthal, Philadelphia—I should like to ask Dr. Griffith if the cases that recover are either right-handed or left-handed. Again, with regard to the treatment, I should like to know if, in the severe cases, hot baths were used. Still another question, is lumbar puncture practiced more than once in the same case?

Dr. Rosa Engleman, Chicago—I should like to ask Dr. Griffith whether any eye examinations were made to determine the condition of the fundus. I have in mind a case of cerebrospinal meningitis in which this was done, and the findings in the fundus were absolutely negative.

Dr. Thomas J. Acker, Croton-on-Hudson, N. Y.—My observation has been that the disease is usually ushered in during the night. The child will go to bed perfectly well, and the next morning will be found very ill. I have seen fifteen or twenty cases that have begun in this way. My experience has been that three remedies can be used with benefit One of these is the bromid of potassium for the convulsive stage; another is the tincture of gelsemium, and the third is Fowler's solution of arsenic. These three remedies judicially used have given me the best results in the treatment of cerebrospinal fever.

Dr. J. P. Griffith—In the title of my paper I used the words cerebrospinal fever rather than cerebrospinal meningitis, not because I am convinced that there is any essential difference, but because my cases, with one exception, were all illustrative of the epidemic type. I have seen a great many more cases in which I could not trace the disease to infection from another case.

Kernig's sign was searched for in some of the cases, but was not present. I am obliged to confess that I am becoming extremely skeptical as to the value of this sign, for I have found it repeatedly absent in many cases of meningitis of various forms. When present, it is of service as corroboration, but when absent we have no proof from that fact alone that the disease is not meningitis. Some of the cases reported occurred before our present interest in Kernig's sign developed.

In connection with the deafness in one of the cases reported, it is an interesting fact that in one institution for deaf-mutes in Germany more cases were due to cerebrospinal meningitis than to any other disease.

The resemblance of cerebrospinal meningitis to typhoid is sometimes particularly striking. I have seen cases which I was sure afterward were typhoid, but which at first I was positive were cases of meningitis.

In answer to the question asked about the likelihood of contagion in the disease, I would say that when the cases of the first family came to the Children's Hospital they were put into a separate room because we did not wish the board of health to take them from the hospital, but that after this danger had passed we put them into the general ward, for, I believe—and I think it is the general opinion—that the disease is no more directly communicable in hospital wards than is typhoid fever. There have been cases reported, it is true, in which the disease has been communicated, but these have been very few and exceptional.

I have been struck with the amount of opisthotonos present in this disease. Yet this alone is not sufficient to make a diagnosis of cerebrospinal meningitis. The most marked case of opisthotonos I ever saw was found afterward to have been due to tubercular meningitis, as shown by lumbar puncture. In another very extreme case there was congenital spastic diplegia present. Lumbar puncture showed no germs. An autopsy could not be obtained.

As regards the employment of lumbar puncture, I agree very thoroughly with what has been said by Dr. Rotch, but I am rather pessimistic as to the real therapeutic value of it. I have never seen any permanently good results from it. Yet as long as there is the slightest hope the procedure should certainly be persisted in. I have done it in cases of tubercular meningitis, hoping for nothing more than temporary relief, and this was, indeed, obtained. Not long ago I was called to do a lumbar puncture on a case at first of doubtful nature, but later found to be tubercular. The child was unconscious, and I removed a large test tube of fluid. A very little while afterward the child was able to speak its mother's name. A few days later I repeated the procedure because the child was again worse, and immediately after this the child was able to swallow food. A third time it was done, but without improvement. I had one case in which there had been a meningitis months before. The child had convulsions at times, lasting for days. These would always be relieved by lumbar puncture, and the child would be better perhaps for several weeks. The case went on in this way for months, but the exact termination I can not recall, except that the child did not eventually recover. This has been my usual experience: that no permanent good was to be expected. Nevertheless, I think it should always be done and the patient given at least the chance. I have not had any observations made on the eyes in most of my cases of meningitis, though it has been done in a few instances.

EPILEPSY—ITS PSYCHOPATHOLOGY, AND MEDICOLEGAL RELATIONS.*

H. A. TOMLINSON, M.D.
SUPERINTENDENT ST. PETER STATE HOSPITAL.
ST. PETER, MINN.

Epilepsy, independent of any gross disease or lesion of the brain, to which it is a sequence, has no distinctive morbid histology, so far as known. Gowers[1] says: "In considering, then, the pathology of epilepsy, we must seek other evidence as to its nature than that which is afforded by the negative anatomy of the idiopathic disease, and must draw our inferences from the morbid changes in organic disease attended by convulsion, from the results of experiment, and from the facts ascertained by the clinical study of the disease."

It is seldom that an opportunity is offered for the study of the histology of the brain in idiopathic epilepsy before the development of those changes which are common to all forms of degeneration, and which obscure everything else. The occasional epileptic who dies of some intercurrent disease, during the earlier stages of his epilepsy, does not present any brain changes different from those found in cases where death resulted from a similar condition, but where no epilepsy existed; and the morbid histologic changes in the cortex in those cases where epilepsy has followed gross disease or traumatism of the brain, do not present anything peculiar nor specific. Therefore we have practically no anatomic basis for the psychopathology of epilepsy. However, we have still to consider the probability that those individuals who become epileptic, do so because of some primary defect in the development of the brain which renders the cortical cells in the motor area abnormally unstable; so that causes of disturbance occurring in infancy, during the period of second dentition, or at puberty, may be sufficient to give rise to these explosive discharges of excessive motor activity, which we know as convulsions, and which have a tendency to become habitual. The fact that, in children, disturbances in the alimentary canal are the most common sources for the origin of the conditions which give rise to the convulsive outbreak, suggests that, as a result of the autointoxication, there are developed changes in the nutrition of the cortical cells, resulting in increased irritability and the production of these undue and untoward manifestations of motor activity.

This view of the pathology of epilepsy naturally suggests the mental status of the epileptic, his stability, and the extent of his cerebral potentiality. In accordance with current physiologic speculation, and the interpretation of the results of experiment, there are three general divisions of functional activity in the cortical portion of the brain mass. Impressions from the general surface of the body and tactile sensations are probably distributed indifferently, and coördinated with relation to such activities as they have previously given rise to. The special sense impressions are grouped in the posterior portion of the parietal, the temporal and occipital lobes; this grouping being the natural result of the necessities of their relation; because, to appreciate the significance of a visual impression, for instance, involves not only the necessity of its relation to a pre-existing similar impression, but also the recognition of the other attributes of the source of the impression, as they come through the other special senses; so that their coördination may result in the proper direction of the motor activity which results through the stimulation of the contiguous area in the superior and anterior portion of the parietal, and the posterior portion of the frontal lobes.

The one cerebral function which is least clearly understood, and yet which is the most important: the inhibitory and directory, almost certainly has its seat in the frontal lobes anterior to the precentral fissure; and the nature of this function necessarily implies that this portion of the brain is concerned principally with the function of intellection. We have direct evidence of this in the fact that mental reduction always advances *pari passu* with the destruction or atrophy of the frontal lobes; that is, the smaller the frontal are in proportion with the parietal lobes, the greater the instability of the individual. Considering the functions of the two portions of the brain, this should be obvious, for if the area for the reception of external impressions is disproportionately large so that the intellectual portion of the brain can not control nor direct them into the necessary channels of activity for the preservation of the organism, the result must necessarily be confusion and incoördination. How, then, shall we apply these deductions?

In order that we may understand the psychology of the epileptic, and appreciate what there is that is distinctive, it will be necessary to consider previously the dominant tendencies in his mental development. If he is congenitally endowed with a defective cerebral structure, we have a right to presume that which experience shows to be a fact: the tendency to the persistence of primitive characteristics, reduction in mental capacity, and the reversion toward the characteristics of a lower order.

Assuming that the individual who becomes epileptic during infancy or childhood, is born with an average cerebral potentiality; the development of some pathologic condition which is serious and persistent enough to bring about the phenomena of an epileptic seizure, and the formation of the epileptic habit; is also powerful enough to check or interfere with the development of the plastic brain mass of the child. Following the usual tendency of such processes, that part of the brain will be most affected which is latest in the order of development and most unstable. The result would therefore be the production of excessive instability, and the establishment of an abnormal irritability, with incoördination in the relation of the activities of the different parts of the brain mass. As the obvious result of this condition, there would be a constant tendency toward undue and irregular discharges of nervous energy; and in the presence of a sufficiently powerful stimulus, indefinite and explosive outbreaks of motor activity, instead of those which were uniform, coördinate, and habitual.

However, we are confronted with the fact that the pathologic or physical conditions which are supposed to be the basis of the epilepsy, are common in the life-history of most people. Prolonged high temperature, gastro-intestinal disease, and other causes of convulsion, are common to many infants; as chronic gastro-intestinal autointoxication and cerebral traumatism are to adolescents and adults: and yet relatively few become epileptic. The converse of this statement is also, in a measure, true; because the epileptic habit often owes its apparent establishment to some relatively trivial cause; but, at least in the majority of these cases, it will be found that the grand convulsion which apparently ushered in

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Richard Dewey and H. A. Tomlinson.

1. Epilepsy—Gowers, 2d Edition, p. 214.

the disease was preceded for an indefinite period by attacks of petit mal; or even nocturnal convulsions, which were not severe enough to attract attention by their effects.

It seems necessary to assume, therefore, that no one ever becomes epileptic who has not, what for want of a better name may be designated the epileptic constitution; or, to express the same conclusion in physical terms, a brain mass in which there is a tendency in the cells of the motor area of the cortex, to respond unduly to slight stimuli; thus bringing about an irregular, incoördinate and explosive discharge of motor energy which, if extensive enough, will and does produce unconsciousness from ischemia and shock, just as a blow on the head would. Indeed, it is quite common for insane epileptics, after a convulsion, to insist that some one hit them, and they point to the bruise made by striking the head as they fell, as evidence of the truth of their accusation. It is not probable that so powerful an expression of nervous energy can take place without involving, to some extent, in its effects other portions of the brain particularly, as well as the whole mass generally, as shown by the production of unconsciousness; and this involvement is made apparent by the existence of those manifestations which are termed the epileptic aura; especially that particular form which concerns the subject of this paper, the psychic aura. This form of aura is most common among the epileptics who are hysterical or insane, and may be compared with a dream; as a series of pre-existing impressions incongruously arranged; the vividness of which will depend upon some anticipated or suggested experience of the individual. It is probable that in those cases of epilepsy in which the psychic aura occurs, the loss of consciousness is comparatively gradual, and that the picture formed follows the same course of development, as do hallucination and illusion. The confusion resulting from the approaching cerebral storm, results in the wrong relation of external impressions, to be followed by the formation of a picture in the fast-dimming consciousness, usually untoward, disagreeable, or malevolent; because the nature of the seizure necessarily forces upon consciousness the conception of violence or discomfort; and external impressions of no matter what nature, would liberate in consciousness preëxisting impressions of experiences which had been painful and alarming. There are some cases, however, where there develop out of the physical discomfort attending returning consciousness well defined beliefs with regard to the environment of the victim, and the responsibility of those about him for his condition.

It is true that epilepsy may persist indefinitely and the outbreaks be frequent and extremely serious, without there being any marked mental reduction, but commonly, even in those cases where there is no mental aberration, and especially when the epilepsy has begun early in life, there is a progressive mental reduction, so that some epileptic children are entirely demented by the time they reach puberty. In others the mental reduction is not marked until maturity, when there is developed, as a sequence, a premature senility. This is also true in those cases of epilepsy where mental aberration is associated with the convulsive process. The individual either breaks down during the period of adolescence, in consequence of some profound disturbance, during adult life as from disease, or, more commonly, at the approach of senility. So far, then, as the psychopathology of epilepsy is concerned, we can omit the consideration of those cases in which there is no aberration nor reduction of mental capacity, because the term psychopathology necessarily implies the presence of both.

The more rapid the mental reduction after the establishment of the convulsive habit, the greater the psychic perversion and the more frequent those manifestations of mental aberration which belong to the epileptic; the post-convulsive furor, and automatism. The study of these maniacal outbursts indicates that they are the response to the impelling suggestions of unreasoning fear, following vivid hallucination, usually visual, but sometimes auditory. Or in cases where there is much mental reduction it is the expression of brutal impulse to wanton cruelty, in response to the gross irritation of the convulsive seizure. This latter is, of course, only the persistence in an exaggerated form of the tendency which is one of the most conspicuous survivals of primitive human characteristics. Sometimes these outbreaks, especially in the procursive form, are mere "running amuck," without regard to anything which comes in the way, and with no purpose.

Epileptic automatism implies a lesser degree of mental reduction and the persistence of considerable intellectual capacity. From a psychic standpoint this condition involves the suspension of active consciousness and the projection of activities which have their origin in centrifugally generated stimuli; which in their turn respond, in a regular sequence, to external impressions, without regard to their nature or origin, as shown in somnambulism. The persistence of automatism after the convulsion constitutes what is known as double consciousness. From what we know of the development of the brain functions, it is certain that most ordinary cerebral activities have a definite hereditary representation in the cortex, so that, as the experience of the individual brings them into active use, they become habitual and automatic long before others which are wholly acquired. It is therefore possible, in the presence of some condition which dominates active consciousness, or some defect in the development of the cortical cells, which lessen their potentiality and reduce their capacity, that the functions of relation and coördination of external impressions are for the time being seriously interfered with or even annihilated; and habitual activities, whose acquisition has been aided by heredity, although centrifugally generated, become for the time being the life expression of the individual. In three cases of double consciousness known to the writer the characteristics manifested by the individuals affected were distinctly of the family type; aside from those primitive ones which had to do with immediate self aggrandizement, such as the imperious will, the low cunning, and the lack of moral sense. If chicanery, brutality, or aggressiveness are actively manifested during automatic states the history of the case if carefully studied will show that they are but the exaggeration of traits natural to the individual. Furthermore, it is worthy of note that epileptics in whom automatism or the so-called epileptic psychic equivalent exist will almost invariably be found to be hysteric as well. The term psychic epilepsy has no real significance, because it implies a condition which in the nature of things could not exist; that is, that there was a mental instead of a motor convulsion. It is almost certain that this condition is a post-epileptic phenomenon; where the initial attack is the petit mal, which is obscured by the mental aberration which follows, and is manifested as automatism or a maniacal outbreak. Therefore it is a sequence to the explosion and not its equivalent.

The medicolegal relations of epilepsy cover such a wide field that it is important to understand what we mean by the term before we attempt a classification of those conditions present in epilepsy, which may have a legal bearing or present a legal aspect.

Such relations would imply that, any act of the epileptic which interfered with the welfare of another, or jeopardized the welfare of the epileptic himself, might bring him within the cognizance of the law, to determine, first, as to the nature of the act; next, how far it was habitual under similar circumstances; then the extent to which the epileptic was capable to, and did appreciate the significance of the act or acts, with relation to his environment. Finally, how and to what extent he might be able to appreciate his relationship to his fellows and control his conduct so as not to jeopardize their welfare.

In order to understand these different aspects of the relation of the epileptic to his fellows it will be necessary to understand his position in the family, the community, in society, and those abnormal conditions resulting from his disease, which might interfere with his relations to those about him.

Aside from the convulsion itself, the acts of the epileptic do not differ from those of other men. The question then, is, not the nature of the conduct itself, but how far it is an unnatural and unusual response to the conditions in the environment of the individual which gave rise to it.

The relation of the epileptic to the family does not differ materially from those common to all who are defective or afflicted. Like the hysteric, the epileptic becomes self-conscious, egotistic, imperious in will, and exacting. On account of his condition the family is disposed to yield to him, and protect him so far as is possible from the consequences of his condition or from anything he may do as a result of it. If the parents of the epileptic child do not exercise good judgment, nor appreciate the tendencies which are sure to develop from the lack of proper restraint and judicious training, the result is always serious, so far as the relation of the individual to the community and society is concerned. This is especially true of those epileptics in whom the motor manifestations are transient and slight, while the psychic disturbance is considerable and persistent.

Having been accustomed in the family to dominating its members, to have his slightest desire always acceded to, and to suffer no punishment nor discomfort as the result of any outbreak of temper or aggressiveness which may follow or supplement his epileptic attack, the indifference and want of consideration for his desires and comfort which he finds when he gets out into the world, and is thrown on his own resources, naturally excites his resentment, increases his morbid self-consciousness, and prompts him to believe that the people by whom he is surrounded are not only indifferent to his welfare, but actively aggressive in the manifestation of their dislike toward him.

Under these circumstances the uncomfortable feelings which precede or follow his convulsions, the bruises or injuries he may receive in falling, or his failure to accomplish any set purpose, on account of the want of capacity and persistence, are attributed to the attitude of the community toward him, and he is to that extent a paranoiac.

The persistence of this attitude, with outbreaks of violent temper from slight causes, are usually the first evidences of mental reduction. The loss of intellectual capacity may never go any further, although the mental reduction continues.

If the epileptic has shown evidence of mental aberration preceding or following his epilepsy, and especially if the history of the case shows he has been markedly unstable and hysteric as well as epileptic, the mental reduction, to the point where self-control is easily lost, may be followed by outbreaks of excitement, or the development of persecutory ideas with depression, which characterize the insanity of epilepsy.

Again, none of these manifestations may be apparent, but there may be instead automatism, and its persistence in double consciousness; therefore, the medicolegal relations of the epileptic, paradoxical as it may seem, do not concern his epilepsy but rather the conditions associated with it; not necessarily growing out of it, but on the contrary, probably always due to progressive degenerative changes resulting from the primary condition out of which they both grew.

As a consequence, in determining how far the epileptic may be responsible for his acts, we have to consider, not his epilepsy, but the degree of primary defect in his mental make-up, as manifested by his cerebral potentiality and intellectual capacity.

EPILEPSY: ITS TREATMENT, HYGIENIC, MEDICINAL AND SURGICAL.*

DANIEL R. BROWER, M.D., LL.D.

Professor of Nervous and Mental Diseases, Rush Medical College, and Northwestern University Woman's Medical School, etc.

CHICAGO.

The want of success in the treatment of epilepsy arises from a variety of causes. First, from the speculative character of it, of the pathogenesis of the disease, from the want of careful study of individual cases and the failure to differentiate the various forms, such as the primary essential, the toxic, the traumatic, the accidental, etc., and from the further fact that there is soon established in the epileptic a habit, and this once established is not destroyed by the simple removal of the originating cause of the disease. Not only must the cause be removed, but the habit must be broken up; and then, again, there is present in every epileptic a peculiar mental state characterized by a want of stability, and it is extremely difficult to have him follow any line of treatment long enough and systematically enough to bring about a cure. His tendency is always to fly off at a tangent, reaching out for some kind of treatment that promises more rapid relief.

THE HYGIENE OF THE EPILEPTIC.

The hygienic treatment, so often neglected, is of the greatest importance, and in the primary idiopathic cases it should be disciplinary, pedagogic and dietetic. These patients, who have by inheritance a neurotic diathesis upon which epilepsy has been engrafted, should from the very beginning be taught self-control, restraint of passions and of appetites. They should be obedient, truthful and industrious. They are, as a rule, strongly inclined to indulgence in the stimulating narcotics, tobacco, alcohol and the like. These should be eschewed by them *in toto*. Another point: Their sexual organs are early brought into activity, and they should be warned against the evils of masturbatory and sexual excesses. Their pedagogic training should be carefully directed. As a rule, they do badly in the ordinary pub-

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Richard Dewey and H. A. Tomlinson.

lic school. Many of them are dullards; others are exceedingly brilliant. The ordinary mental condition is less common. Being liable to fits of ungovernable passion, they are often difficult to control, and constitute in their school discipline a very perplexing problem to the average school teacher. Fortunately, there are today a number of excellent private schools scattered throughout the country where these children can receive the special educational training so necessary for the removal of their abnormal instability. This educational training should include physical culture; indeed, this should be emphasized in every case. Through active muscular exercise they can find an outlet for their surplus nervous energies that otherwise might escape in their peculiar convulsive movements. The muscles concerned in the respiratory act can be developed with great advantage in these cases.

THE DIET.

The dietary in all cases of epilepsy should be arranged with care, and in order to do this each patient must be carefully studied as to his or her digestive capacity. The idea prevails among some that the animal proteids should be entirely cut off. My personal experience is against this conclusion, although I am well satisfied that the consumption of this form of nitrogenous food, as of all nitrogenous foods, should be minimized. But there are very few epileptics who are not really benefited by one meal of meat per day. Epileptics usually have a voracious appetite; they eat their food with rapidity and without proper mastication. This must, of course, be corrected, and from the dietary all indigestible articles, such as pastry, fried foods and coarse vegetables, should be excluded. My experience has taught me that sodium chlorid and sugar should always be minimized. I have no doubt that salt starvation results in a more perfect assimilation of the bromids, for I have conclusively ascertained that most of the bromids will control the paroxysms with the salt practically eliminated, and lessened sugar consumption results in more digestion of the nitrogenous foods. I usually furnish my patients with a diet table, of which the following is a model, striking out or adding to special things as the peculiarities of the case demand.

Breakfast.—Oranges; apples, baked; peaches; oatmeal; cracked wheat; hominy, to be thoroughly cooked and eaten with milk or cream; eggs, soft boiled, poached; toast; bread, white, graham, corn; coffee (moderate strength); milk.

Dinner.—Oysters, raw; soup, bouillon, tomato, vegetable, oyster; chicken or mutton broth; meats, roast beef, roast lamb, roast chicken or turkey; fish, fresh, baked; vegetables, potatoes, spinach, carrots, turnips, onions, string beans, lima beans, peas, squash, asparagus (all to be well cooked); bread, farina, rice, tapioca, cup custard; cheese, Edam, American cream; crackers.

Supper.—Toast; crackers; cornbread; eggs; stewed prunes; baked apples; apple sauce; milk; tea (weak); coffee (weak).

Avoid.—Pastry, cakes, nuts, pork, veal, fried foods. Eat moderately. Masticate thoroughly.

THE MANY DRUGS RECOMMENDED.

The medicinal treatment of epilepsy has a most interesting history. Almost every article in the materia medica, as we have it, or as it was known to the ancients, has been given in this disease, and more or less success reported attending its administration. The epileptic is emotional. He is very susceptible to suggestions, and often by the simplest placebo given with a positive suggestion of relief the paroxysms may be controlled for a variable space of time, and thus credit should be given to anything that might constitute a placebo for the relief of the disease. This peculiarity of susceptibility to suggestions is not only often overlooked in making up an estimate of medicinal agents, but it is certainly frequently overlooked in reporting the results of the various surgical procedures that have been employed. Careful attention to elimination should be the foundation of the treatment of every case. Insufficient renal elimination is not infrequently present. Elimination by the skin must be promoted by the use of baths, hydrotherapy and massage. I have a case under observation now in which very satisfactory results are being obtained. The patient had been treated with the bromids to the extent of saturation, without any results except marked mental impairment. The epileptic seizures continued. A careful study of his case, running through some days, determined the fact that before his paroxysms occurred especially there was insufficient elimination of urinary solids and a very marked defect in the amount of urea. Treatment addressed to this peculiarity of his case, the entire withdrawal of the bromids and the substitution of moderate doses of antipyrin, while it has not cured him, has yet given him the longest interval that he has had in ten years between his paroxysms, and has restored his mental integrity.

Intestinal elimination and intestinal cleanliness are of great importance. We should so regulate the diet as to produce a minimum amount of intestinal fermentation. Of the use of intestinal antiseptics, salol and the new salicylate, aspirin, are probably the best.

The use of lavage and of colonic flushing, thereby cleansing both ends of the chylopoietic viscera, is not to be overlooked in any case, and laxatives, of which the aloetics are my favorites, with occasional doses either of blue mass or calomel, are aids to intestinal elimination and asepsis.

THE AURA.

The next important thing in the matter of treatment is to determine whether or not there be present in a given case an aura. If an aura is present and can be successfully treated, it is a wonderful aid in breaking up the epileptic habit, while the other treatment may be correcting the cause upon which the neurosis depends. For this purpose the nitrite of amyl is the most successful agent, and the pearls of various sizes that are furnished to us by the pharmacist serve the purpose the best; and the amount of nitrite of amyl necessary to break up or prevent a paroxysm in any given case can only be determined by trial. Some aid in this matter is given by the use, where it is practicable, of counter-irritation. If an aura begins in the extremities, counter-irritation of that extremity by the actual cautery or by blisters, or sometimes by the use of some other irritation, is effectual. I had, a few years ago, a patient whose aura began in his hand. He wore around his wrist a bracelet of silk, which was so arranged that on the first approach of the aura it could be quickly tightened, and this suddenly-applied irritation was usually sufficient to prevent the development of the convulsive seizure. Anything that will produce a sufficiently powerful impression upon the sensory end organs of the place from which the aura seems to proceed will sometimes answer the purpose. But the aura should always be inquired into and never overlooked, if present, as an important means by which treatment can be instituted which will prevent the formation of an epileptic habit in recent cases and assist in breaking it up in the chronic cases.

THE USE OF BROMIDS.

I think we are all agreed that the most generally useful remedy for internal use is the bromids. The bromids give relief, more or less, in at least 80 per cent. of the cases. But there is a percentage of cases, certainly not less than 10 per cent., in which my experience teaches me that the bromids not only give no relief, but do damage. In the administration of the bromids in every case great care must be exercised that the dose is such as will not produce mental deterioration, for it is very much better for the average epileptic to have an occasional explosion with mental integrity, than it is to be relieved of all explosive efforts, with mental enfeeblement. The bromid which I prefer is the bromid of sodium. I have failed to see any particular benefit from a combination of the various bromids, and in my clientele I have seen no advantage from the use of bromid of strontium.

The bromid should be administered in some one of the mint waters, changing the vehicle from time to time, in order that distastefulness for the combination may not be established in any case. For children my rule in the administration of the bromids is to give a grain for each year of their age. In adults I rarely exceed twenty grains, three times a day, and in every instance advise that the bromids be taken after eating. In recent cases that have not been under the bromid treatment there may be reason for pushing the bromids to the extent of complete bromism, beginning with twenty grains, three times a day, and each week increasing the dose up to complete saturation. But this condition of things should in no case be maintained except for a short space of time, and, in my judgment, is only applicable to cases in which the disease has just recently developed.

If the dose of bromid that has been specified fails to relieve the patient, I add to the treatment the fluid extract of *Solanum Carolinensis*. It is a synergistic remedy. Beginning with half-teaspoonful doses it may be pushed to two-dram doses, and it will, without any mental deterioration, sometimes relieve the paroxysms. In some cases, especially where there is cardiac enfeeblement, and this is the case with very many epileptics, the fluid extract of *Adonis vernalis*, in from a half to five minim doses, may be added with advantage to this combination, and relief obtained without pushing the bromids beyond the sixty grains per day already indicated. If this combination fails to relieve the patient, and the other important aids to treatment have been carefully attended to, some one of the coal-tar analgesics may be added to the treatment, as acetanalid, phenacetin, antipyrin, and if these several combinations fail to produce the desired result, with the bromid and *Solanum Carolinensis* treatment may be added the use of belladonna, and probably the best way to administer the belladonna is according to the Trousseau method. Trousseau's formula is:

℞. Extracti belladonnæ .....gr. 1/5
Pulv. folia belladonnæ .....gr. 1/5
For one pill.

During the first month the patient takes one of these pills every day, in the morning, if his attacks occur chiefly in the daytime, or in the evening, if they are chiefly nocturnal. One pill is added to the dose every month. The drug should not be pushed beyond excessive dilatation of the pupils, and uncomfortable dryness of the throat. While the patient is under the bromid treatment, attention should be given from time to time to the condition of the blood and the anemia that belongs to the disease naturally, and which is often very much intensified by the use of the bromids, should be combated. The bromid of iron is a very good agent with which to do this, as is also liquor ferri et ammoniæ acetatis, and sometimes the correction of this anemia will make the treatment, otherwise unsuccessful, satisfactory. The anemia of these patients may sometimes also be combated by the use of cod-liver oil. Especially is this true of treatment during the winter months. The alkaline bromids produce, after a time, in some cases an irritable condition of the bladder, then the bromohydric acid should be substituted for a time, or the new combination of bromin with oil of sesame, called bromipin, may be used.

THE TREATMENT WHEN BROMIDS FAIL.

Where the bromid treatment fails, some have had success from adding to it borax in ten-grain doses, three times a day, but my experience with borax has not been very satisfactory. Occasionally, where the bromids fail with the combinations already suggested, the bromids may be continued and the oxid of zinc in from three to five grains may be added to the treatment with benefit. While under this treatment, even where only a small dose of bromid is administered, as I see in my own practice, the patients will, of course, complain very much of the bromid acne. Especially will this be the case with women, and this may sometimes be overcome by the use of preparations of arsenic. If the bromid of sodium is administered, the liquor sodii arsenatis in from three to five minim doses may be put in the prescription already indicated, and arsenic is not only a benefit to them for this reason, but as a tonic alterative to the nervous system it is often of very great service. In epileptics with poor circulation in the extremities, a condition that will be often very much exaggerated by the use of bromids, strychnia will be of service, in from one-sixtieth to the twentieth of a grain, administered three times a day, as a substitute for one of the adjuncts already suggested.

COUNTER-IRRITATION FOR HEADACHE.

In the cases that complain much of headache, as in some cases that do not, cauterization of the neck is of service. Counter-irritation is entirely too much neglected in our present therapeutic methods. Cauterization of the neck may be done by the actual cautery, and sometimes, when the medicinal treatment already indicated fails, the addition of the actual cautery to the neck, two or three times a week, will secure the results desired. Where the use of the actual cautery is not practicable, a silver wire suture inserted into the neck will accomplish the same purpose. In a percentage of cases in which bromids fail or are detrimental, relief may sometimes be had by treating the cases on the Tyrell plan, by giving strychnia in gradually increasing doses. I have had a satisfactory experience quite recently in a case in which abortive epileptic manifestations were occurring almost daily. Under the use of full doses of strychnia, twice a day, he has now had exemption from these attacks for about a year. I began with him with the sixteenth of a grain of strychnia, twice a day, and carried it up to the tenth of a grain, and along with that gave him aloetic laxatives, and with such hygienic and dietetic treatment as were indicated. In this man's case the bromids were positively detrimental.

OTHER DRUGS SOMETIMES VALUABLE.

I have already mentioned a case in which the use of antipyrin, with attention to renal elimination, is producing satisfactory results where the bromids were harmful.

Dr. G. Frank Lydston[1] has reported successful results from the use of santonin, beginning with two-grain doses, three or four times a day, and increasing the amount to the point of tolerance, which, in many cases, is about fifteen grains. A rather limited trial of Dr. Lydston's method indicates that in those cases where the bromids disagree it may be of great service, and a further trial of it is demanded.

The late Dr. Pepper of Philadelphia reported cases in which bromids had disagreed with patients, but which were benefited by the use of sodium salicylate and antipyrin.[2]

The syphilitic cases of epilepsy require, in addition to the moderate use of bromids, the most vigorous administration of the iodids that is compatible with the general nutrition of the patients, together with the hypodermic administration of mercury.

Some of the rebellious cases are benefited by the use of nitroglycerin, using a 1 per cent. alcoholic solution, and giving from two to ten minims morning and evening. Pellegrini has recently published some very satisfactory results from the use of nitroglycerin in these cases.[3]

SURGERY.

Surgical treatment, which offers to relieve primary idiopathic epilepsy by any operative procedure yet suggested, must necessarily always be a failure, and there is nothing whatever in the records of sympathectomy, or in ligation of the vertebrals, or in trephining that will justify us in recommending it in a single case of this sort. The traumatic cases can undoubtedly be benefited, not cured, by operative procedures, provided the epilepsy has not been of too long duration, and too many convulsions resulting. I should place the limit of time at which an operation would be successful at two years, and these traumatic cases that have received surgical attention require none the less the treatment that has been previously indicated for breaking up the habit and against the neurosis. But in all of these surgical procedures, no matter whether they be done for a primary idiopathic case or an acquired case, for reasons already given, temporary success will follow an operation by its inducing temporary inhibition of cortical cells, as has been suggested by Putnam. The literature of the subject is filled with alleged cures of epilepsy that have been affected within a short time after a surgical operation, and I have in my clientage to-day some of these cases of alleged surgical cures, and am treating them with benefit by the hygienic and medicinal treatment already indicated.

TREATMENT OF THE SEIZURE ITSELF.

As to the treatment of the epileptic paroxysm itself, but little need be said. The patient should be placed in the recumbent posture, with the clothes loosened about the neck and body, and efforts made to prevent biting the tongue. If the epileptic status becomes established, chloroform by inhalation and hyoscin hydrobromate by hypodermic injection will give the most prompt relief. An excessive amount of treatment applied to the epileptic attack itself, which we sometimes witness, is worse than useless.

Position of Ulnar Artery.—In making incisions in the wrist and forearm, always ascertain, if possible, whether the ulnar artery, instead of running under the superficial muscles, passes over them, as is frequently enough the case.—*Toledo Med. and Surg. Rep.*

INSTITUTIONS FOR EPILEPTICS.*

WILLIAM P. SPRATLING, M.D.
Medical Superintendent of the Craig Colony for Epileptics; Secretary of the National Association for the Study of Epilepsy and the Care and Treatment of Epileptics.
SONYEA, N. Y.

HISTORICAL SUMMARY

As long ago as 500 years before the dawn of the Christian era epilepsy was known and described, but the epileptic as a public charge was completely neglected until the latter part of the seventeenth century, when individual efforts were made in continental Europe to improve his condition, though without any uniform results until about the beginning of the century just passed. In 1846 France took the lead in establishing a small colony for epileptics and other defectives at LaForce, near Bordeau, to be followed by Germany in 1867, when the now celebrated colony at Bielefeld, in the northwestern part of the empire was begun with four patients in one hut, and which is still the leading institution of its kind in the world, now caring for nearly 1,800 sufferers from epilepsy and over 3,000 defectives, including the epileptics, of various other kinds. Next came England in establishing in 1888 the Maghull Home for Epileptics near Liverpool, and later the same country created the very excellent colony at Chalfont St. Peter, some twenty miles from London; while still later the Meath Home at Godalming, in the beautiful country of Surrey, marked the third institution for epileptics in the British Isles, all of them, like their predecessors on the continent, being founded through private generosity.

Just prior to this, in 1887, Peterson discussed the advantages of the public care of epileptics in America on the colony or village plan, drawing his ideas and inspiration from a visit to the colony in Germany, and in 1890 Ohio took the lead over all other American states and founded the Ohio Hospital for Epileptics and the Epileptic Insane at Gallipolis, to be followed four years later by the state of New York, which set about at that time to create the Craig Colony at Sonyea, in Livingston county, the first institution of its kind for epileptics on the western hemisphere. Simultaneously with the movement in New York, Massachusetts and New Jersey took up the question, the former founding the Massachusetts Hospital for Epileptics, at Palmer, the latter the New Jersey Village, at Skillman, some five miles from the university town of Princeton. About the same time Pennsylvania established an epileptic colony and hospital farm at Oakbourne, not far from Philadelphia, and Texas felt a generous desire to join the fast-spreading movement by laying out an epileptic colony covering some 640 acres at Abilene. Other states, the most notable among them being Virginia and Illinois, have made strenuous attempts to take care of epileptics, and so earnest and persistent have been the efforts of Dr. Drewry and his colleagues in Virginia and Miss Lathrop and other members of the Board of Public Charities in Illinois, that it is only a question of time as to when these progressive states will have institutions for epileptics that will rank among the best.

To John Bost, in France, Von Bodelschwind, in Germany, Peterson, Letchworth and Craig, in America, and to the National Society for the Employment of Epileptics in England, belong the credit of taking the lead in

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Richard Dewey and H. A. Tomlinson.

seeking to improve the deplorable condition of this long-neglected class.

IN AID OF THE WORK IN FUTURE.

The great problem of devising and pushing forward a more wide-spread interest and system of state care for epileptics in the United States is a serious one, in which doctors and philanthropists might well labor together in perfect harmony and with unflagging zeal. No other class so strongly demands public aid, and no class has been subjected to such neglect.

Of the forty-five states in the Union, five only have made state provision for epileptics, and these five at the present time are caring for less than 2,000 patients —2,000 out of at least 150,000 scattered throughout the land; hundreds of them unjustly confined in hospitals for the insane; thousands in county poor and almshouses, the victims of neglect, constant suffering and despair; while by far the larger number remain in poverty-stricken homes, the subjects of solicitous and painful care on the part of those who refuse to send a human being, sick in this way, to a poorhouse intended only to give aid to paupers.

To further stimulate the work in this country, the "National Association for the Study of Epilepsy and the Care and Treatment of Epileptics" was organized in 1898 for these purposes: "To promote the general welfare of sufferers from epilepsy; to stimulate the study of the causes and methods of cure of this disease; to assist the various states in America in establishing a uniform system of care for epileptics; to advocate the care of epileptics in institutions designed for their especial needs;" and the transactions of the first annual meeting of this association, recently published, may be of value to those interested in the work, while "The Care and Treatment of Epileptics," by William Pryor Letchworth, LL.D., is a singularly complete treatise of the whole subject at this stage of its development, both here and abroad.

A LITTLE INDEFINITE CONSTRUCTION AT THE OUTSET UNAVOIDABLE.

The history of the building of institutions for the insane will be repeated in a measure in the building of institutions for epileptics. Methods that are satisfactory in every respect will not be adopted at first, for we require experience, and there has been but little opportunity for acquiring any to this time—that is, but little up to within a very few years ago, and we have found that however excellent foreign methods and ideas may be, they need to be remodeled to make them serve the best purpose under American conditions. Whatever mistakes, however, we may make will be in details only, for it has been quite conclusively shown that the colony system of caring for epileptics is correct; and while the work of building for this class is not yet a finished art, I know of no problem in it under present requirements that can not be satisfactorily solved if the opportunity is only given.

SOME KNOWLEDGE OF THE ECCENTRICITIES OF EPILEPSY OF FIRST IMPORTANCE.

Before an architect can successfully plan a house, he must know what it is to be used for, and since the epileptic stands so supremely alone in the form of his affliction and its results, his proper care demands special homes of many kinds. He represents marked differences in age, character and frequency of attacks, race, social status, habits and, what is most important of all, in forms and degrees of unsoundness of mind, and it is his mental condition in the main that fixes the manner in which he should live.

Fully 80 out of every 100 epileptics acquire the disease before they reach the age of 20 years, and affecting the brain, as essential epilepsy in time always does, we must expect some impairment of the mind, either fixed or temporary, slight or profound, in every case in which the disease is genuine. Out of every 100 epileptics studied at random, in institutions and out, 5 to 10 per cent. of them will have sound minds; 15 to 20 per cent. of them will be insane, while the remaining 70 to 80 per cent. will have mental enfeeblement in some degree.

On April 18 last the chief physician of the German colony at Bielefeld made a classification of the 1,771 epileptics under his care for us as follows: Sound minded, 98, or 5 per cent.; weak minded, 1,100, or 62 per cent.; minds diseased, 582, or 33 per cent.; and of the entire number, 800 only have their freedom, while at the Craig Colony the ratio of those kept in isolation to those who have full liberty is much less, because of greater care in selecting new admissions.

To build institutions for the epileptic without remembering that his disease is psychic as well as physical, is to invite serious disaster. The superintendent of the Massachusetts Hospital for Epileptics, in his report for 1901, says: "It is found to be more difficult to deal with epileptics than with the insane. In many ways our class of adult patients possess to a large degree the mental and emotional traits of children." Dr. H. C. Rutter, for many years superintendent of the Ohio institution for epileptics at Gallipolis, says: "While it can not be said that all epileptics are insane, still in a considerable majority of cases the mind is so frequently affected that a limited supervision is absolutely essential to prevent their entire submergence. It must be remembered that epilepsy is not altogether a physical disease; it is psychic also;" and were it necessary I might present facts in plenty to show that we can not afford to neglect the condition of irresponsibility common to epilepsy when we build institutions for them, no matter what may be the type of his disease.

THREE KINDS OF INSTITUTIONS REQUIRED.

To get the best results, epileptics should be cared for in institutions of three kinds: First, hospitals for those that are insane; second, colonies for selected cases only; third, colonies for all cases save the insane. (It is entirely feasible to merge the two kinds of colonies into one, but the results are then less satisfactory than if they are kept separate and distinct.)

The leading features of hospitals for insane epileptics need not differ much from those observed in building for the ordinary insane, although there are some things we ought especially to take into account, and of these classification comes first. No matter if the epileptic is insane, he is an epileptic still, his convulsions do not cease and he is most apt to make trouble during his seizure periods. Already violent to a marked degree, his violence is apt to increase at these times and efficient means are required for his safe keeping until his excessive frenzy passes away. It has been my experience that more durable forms of construction are demanded in the care of some insane epileptics than for the ordinary insane, and while hundreds of cases may be cared for in one building, or in a compact group of buildings, living apartments should be planned to admit of necessary classification. On this point Dr Flood, of the Massachusetts Hospital for Epileptics, says: "I do not believe in putting twenty-five people in one dormitory.

It works much better when we classify them by putting not more than four or five to sleep in one room." Congregate dining rooms for epileptics will not do. I have known a single fit in a dining room that seated 100 to lead to disastrous results through sympathetic shock in causing five or six other seizures in the room in rapid succession.

Some special features, such as broad, rounded corners on all woodwork, the breaking of stairways with two or more landings and the protection of all heating pipes and radiators should be provided for. Two-story buildings are infinitely to be preferred to those that are higher, and there is no objection to having some bedrooms on the first floor.

The problem of night supervision is as important as its solution is difficult, and this applies to epileptics of all kinds. I once saw the experiment made, through necessity, of having twenty-eight epileptics sleep in one large room. This made it easy for the night nurse to detect anything wrong, but in all other ways it could not possibly have been worse. Fits occurred almost hourly, and the noise incident to each seizure wakened all the sleepers, and after this had been done six or eight times in a night the frame of mind the next morning of those who had to endure it can be better imagined than described. In our opinion, it is not possible to devise any sort of night supervision that will entirely do away with the epileptic's liability to accident while he sleeps, unless every room is provided with a nurse in charge. I recall two patients during the past year who died in bed as the result of fits that occurred between the half-hourly visits of the nurse, and we have come to believe that it is much better not to put more than five or six to sleep in one room and run the risk of an occasional accident than to make vast numbers habitually uncomfortable by herding them in huge dormitories in which repeated attacks destroy the comfort of all the rest.

COLONIES FOR SELECTED CASES ONLY.

There are no colonies for selected cases only in this country at present, and because such institutions might seem to be too discriminative in the work they do the state might hesitate to build them. Such colonies have a high value, a value which they can, perhaps, best reach under the stimulus of private benevolence, and there is a splendid opportunity for people of means to take up such work in the United States at this time. There should be such a colony in easy reach of every city in this country having a population of half a million or more. They should not be large—big enough only for 100 to 200 patients; the one great valuable feature about them being individual attention to a class that promises most, under proper care, in the way of improvement or cure, a class that is now submerged in institutions that care for hundreds of cases to whom we can promise but little or nothing for to-morrow.

Colonies like these would bear the same relationship to other colonies or institutions for epileptics that psychopathic hospitals bear to other institutions for the insane. A type of such an institution is to be found in the English colony at Chalfont St. Peter founded by the National Society for the Employment of Epileptics. It has now about 135 patients, and Dr. William Aldren Turner has this to say about the manner of selecting cases: "It has been found advisable to carefully select the colonists from among a large number of applicants. The points to which attention is especially directed by the medical committee are: Has the applicant been unable to obtain employment, or has he been discharged from one or more situations by reason of his fits? Is he capable of work under direction? It has been found necessary to regard as ineligible those who from physical causes are not strong enough to undertake some kind of active work; those who from habitual irritability of temper and eccentricity of disposition would not live in harmony with their fellow inmates or be amenable to the rules and regulations of the institution, and especially those who are imbecile, demented or liable to dangerous impulses. Mere frequency or severity of fits, however, does not disqualify the applicant, provided the mental condition is satisfactory." This process of exclusion, we are told by Dr. Turner, shuts out about 60 per cent. of all who apply, and the work at Chalfont St. Peter has been entirely satisfactory. It seems to me that no finer plan can be devised for the care of epileptics who can do some work under proper supervision than this, and of the plan and probable cost of building and maintaining such colonies we will speak later on.

COLONIES FOR ALL SAVE THE INSANE.

The word "epileptic" conveys to one unfamiliar with the many types, causes and results of the disease but little information we ought to have before we can successfully plan for the epileptic's best care; and the epileptic who voluntarily seeks help of the physician at his office is seldom representative of the class most apt to come under state care, and in taking all epileptics save the insane into one colony many problems will engage our attention. The majority who apply will be mentally defective in some degree, either feeble-minded, or imbeciles, or idiots, while some will be demented and a few will have sound minds; and while we can not sharply separate them into like groups, because the lines of separation are so vague and so constantly shifting, we can approximate the groups fairly well.

In studying how we might best classify 1,200 mixed cases that have been admitted to the Craig colony to this time, we have found it feasible to put them in houses of three kinds. Houses in class one hold from 12 to 16 or 18 patients whose condition is good enough in every respect to enable them to assume the care of the household in all its details, under the general supervision of one competent nurse or employe, the chief duties of the latter being to look after sick patients and to make observations of seizures, to be reported to the physician in charge. Houses in class two should be large enough to accommodate from 25 to 35 persons of the great middle class, and each house should be in charge of two employes, nurse and cook, and the bulk of the colony would be made up of houses of this type. Houses in class three should consist of infirmaries; buildings combining home and hospital, for the use of perpetually bed-ridden, paralytic or otherwise helpless cases. These buildings need not be large at the outset if care is exercised in selection of cases, but they should be so constructed that they might be enlarged in future.

THE WORTH AND QUALITY OF EPILEPTIC LABOR.

In such a colony about 50 per cent. of all admitted can do work of a remunerative kind; about 25 per cent. will be able to do light housework only, and the remainder nothing at all; while the labors of 7 per cent. to 10 per cent. of the entire number will have a value equal to, or greater, than the cost of their support, and we have come to believe that under the best conditions colonies for mixed cases may be able to earn from 25 per cent. to 30 per cent. of the cost of their maintenance, while colonies for selected cases only may reasonably aspire to do about twice as well.

Epileptics can work at almost anything, though some can be employed at occupations that are hazardous with greater safety than others. In seven years at the Craig colony we have never known a serious accident to follow a risk in occupation, and our patients do everything from needlework to house painting and engine driving, though special cases are selected for special work.

Colonies for epileptics should therefore provide the fullest equipment of all industries common to normal communities and should employ skilled artisans to train and supervise epileptic labor, both for economic and therapeutic reasons, but especially for the latter. The epileptic who is idle is badly handicapped in the race for improvement in comparison with the epileptic who is kept at work, and colonies should be kept free from the atmosphere of invalidism.

LOCATION, SIZE, COST AND PLAN OF DEVELOPMENT IN THE CONCRETE.

Location.—In looking for a site it should be announced that gifts of land will not be considered, for when the state accepts such gifts embarrassments are apt to always follow, and in choosing a site two things should be prominently borne in mind: First, the natural advantages of the place, including water, climate, fertility of soil and drainage; second, reasonable proximity to centers of population; but if it is a question as to which should determine the matter, those named first have the greatest weight. It is impossible for a colony to meet with success unless its water supply is pure and abundant; its climate such as to insure the greatest number of pleasant days in which outdoor life is possible with comfort; in which the fertility of the soil under cultivation by epileptic labor insures the largest yield; and in which diseases due to faulty sanitation are lessened by perfect drainage.

Size.—It is difficult to say how large a colony should be, but as a rule an acre to each individual will be none too much. The epileptic's food should come almost exclusively from the farm, dairy and garden, which makes a large amount of fertile land a prime necessity.

Cost.—The cost of a colony equipped for use can now be pretty definitely ascertained before the work of its construction is begun, if the cost of the land only is known. Durable brick and stone houses for patients will cost about $500 per bed, while the cost of furnishing will vary from $30 to $50 per person. About one-half the cost of the colony will be in the houses, the balance in plants to supply heat, light and water, in administrative offices and hospitals, in furnishing, in industrial shops, farm stock and implements, sewerage system, roads, walks, grading and homes for officers and employes. There is no valid objection to building some houses of wood, if they can be made small, properly located and protected against fire, and they can be made ready for occupancy at one-half the cost of brick and stone buildings.

Plan of Development.—So far as possible a definite plan of development should be followed by making a complete topographic map of the land at the outset, always remembering the value of approximating the main features, and we may illustrate the method of doing this by drawing a circle of sufficient diameter and putting in it the office building, the hospital, the power plant, storehouse, laundry, schools, industries and other common necessities, then draw another circle and let that embrace homes for the better classes, and then a third, beyond which home for the poorer types of colonists should not go. By doing this it will be easy to heat, light, furnish with supplies and supervise the entire colony from a central point at less cost than if the essential features were scattered indiscriminately over the entire place. Local conditions may call for some modifications of this, but in the main the principle will be found correct. The exterior design and color of cottages for patients may be all alike, or no two may be the same, the determination of the point resting on individual preference. At Bielefeld and Chalfont St. Peter the buildings all differ; at the Craig colony the two main groups of fifteen to twenty buildings each are almost identical in form and entirely so in color. The cost of maintenance for mixed classes after the population reaches 600 to 700 will be less than for the insane, while colonies for selected cases only should not require more than $75 to $80 a patient a year, and under ideal conditions even less.

Young epileptics, whose minds admit of it, require some education, which needs to be simple, for, as a rule, they are unable to grasp and retain complicated ideas, and it has been our experience that purely intellectual knowledge acquired by them to-day is apt to be lost through the destructive effects of a fit to-morrow; but that when tissue grosser than the brain, like muscle, learns a thing well, that knowledge is not destroyed with each fit; therefore, we have come to believe that the combined use of muscle and brain should be the favored method of educating this class, the value of the former compared with the latter being fully as great as ten to one.

MONEY FOR RESEARCH WORK.

The clinical picture of epilepsy seems complete, but its two most important objects of study have as yet scarcely been touched upon: the morbid psychology and the etiology of this mysterious disease; and such work can best be done in institutions for epileptics, because it is only here that the necessary wealth of material can be found. It is well, however, for us to understand at the outset that such work, to be of value, can not be done without considerable cost, and in states in which expenditures for the maintenance of public charities are already of great magnitude, we ought to try and enlist the aid of private wealth, and I venture to add that the interest on an endowment fund of $100,000 in two or more states to-day would be most valuable gifts for the purpose.

In conclusion, it is unnecessary to add that my aim in this paper has been rather to try and lead into prominence some of the more important principles involved in the institutional care of epileptics, based on the epileptic's condition, than to recite material details that are only of value when the work of construction has commenced; nor to add that the sure test of time has conclusively demonstrated that institutions, especially colonies, for epileptics have so amply justified their creation as to make the establishment of one desirable in every state in the Union. Let us co-operate to help the work along.

DISCUSSION

ON PAPERS OF DRS. PEARCE,* TOMLINSON, BROWER AND SPRATLING.

ETIOLOGY.

DR. J. D. MCCARTHY, Philadelphia—So far as pathogenesis of epilepsy is concerned, I think we could better understand the subject by saying that we do not know anything about it. Several theories have been advanced, but they are purely theoretical in the present status of the anatomy and physiology of the brain. The theory that has been gaining ground in late years of the toxemic process can explain very little of the pathogenesis, if you do not assume the instability of the cor-

* The paper of Dr. Pearce was published elsewhere.

tical cell. Assuming this, it is a theory based on a theory, and so on until you finally arrive at a stage where you reach a conclusion based on several theories. The toxemic theory is probably the theory that best explains the development of the epileptic attack. There again, if you try to explain the individual elements of the attack you assume a former theory, i. e., the vasomotor theory. These theories have been separated by different observers and they all pass one into the other. I think that any one who has much to do with a large number of epileptics can not get away from the fact that whether the attack results from autointoxication of gastrointestinal type, whether it be one of the so-called alcoholic cases, or whether the origin of the condition is unknown, many of these are really of reflex character. The development of the convulsion in these cases is paroxysmal. There is usually before the spasm an instability of the cortex and an instability of the motor mechanism, followed by a discharge of motor energy. This groundwork of these explanations has been given to the profession by Dr. Jackson, who probably understands more about the subject than any other man. This instability, it seems to me, we see especially in the alcoholic cases. There is a certain defective organic development of the cortex, which you can not see microscopically, but there are other evidences of degeneration scattered throughout the brain, owing to its susceptibility to the action of the toxins. You can very easily see how, in a case where the motor mechanism is so finely balanced, it would be easily overthrown. You can easily see how a small amount of alcohol or a small amount of other intoxication could produce an epileptic attack under these conditions. In the cases where the patients will probably have an attack every four or five years these attacks will very often be associated with conditions of autointoxication. The cases resulting from intoxication from alcohol can probably best be explained on this same ground. These cases should be distinguished also from another sort of convulsion which should be differentiated from true essential epilepsy; i. e., cases rather of an organic affection (brain tumor, etc.).

THE MEDICOLEGAL ASPECT.

DR. A. B. RICHARDSON, Washington, D. C.—The mental deficiency or disorder connected with epilepsy or resulting from it may be naturally subdivided into several forms. The first is that congenital defect which shows itself in retarded and imperfect mental development and of which the epileptic attacks are only another expression. In these, while the convulsive seizures may have the effect of increasing the degree of the mental deficiency or disorder, the original defect is, after all, the chief point to be investigated, and this is not materially affected by the epileptic complication. In other words, imbecility without epilepsy and imbecility in which epilepsy develops as a complication, do not very materially differ in their symptomatology so far as the mental deficiency is concerned. The degree of legal responsibility is therefore to be determined in such cases rather by a study of the mental deficiency than by anything peculiar in it traceable to the convulsive attacks.

A second class of cases are those in which the first evidence of disease is the occurrence of epileptic attacks, commencing in the early years of life and apparently largely by their influence on brain nutrition resulting in imperfect mental development and in various degrees of mental disorder. Here the form of the deficiency or disorder is more likely to be influenced by the epilepsy and requires more consideration in this investigation. In such cases the mental disorder is more likely to vary in degree from time to time and to be accompanied by violent outbursts. The epileptic disposition, so marked in its characteristics in many cases of later development, is more noticeable. There is greater irritability, sometimes more extreme dementia, and there is more likely to be present also a greater degree of suspicion. There is, I believe, also more obtunding of the moral sensibilities of the patient. He is more unreasonable and less easily controlled. The influence of the epileptic seizures themselves is more marked, and the mental phenomena are more paroxysmal in character. It becomes necessary not only to consider the permanent imbecility present, but also the kind of variations in the mental state occurring periodically and bearing some sort of relation to the convulsive attacks. They may precede, follow, or take the place of these. There may be several days or weeks of excitement and changed emotional states followed by conditions of greater quiescence and continually increasing mental weakness. In all these cases, however, there can be but little trouble in determining the irresponsibility of the patient. The permanent mental defect makes this evident, and the only question remaining is usually how far the irresponsibility shall be extended in a given case. In the presence of a permanent mental deficiency, any given act should be studied especially in the light of the motives prompting it. It is seldom in such cases that these motives are not influenced by the defective reasoning arising from the permanent deficiency. In the cases where the imbecility is but slightly noticeable the temporary perversions of the state of mind accompanying the epileptic seizures become more important in their medicolegal aspect and call for careful study. In a small percentage of such cases a marked criminal propensity is developed in the child, a vicious disposition or a tendency to injure animals and playmates without any corresponding provocation. Those moral monstrosities arising now and then in a few instances have an epileptic history. I believe these are rare, however, and the rule is that epilepsy, during the developmental period, has a tendency to cause periodical excitement or irritability with outbursts of passion, and in these oftentimes homicidal impulses, but does not develop in the person fixed propensities toward crime. There is usually a gradually progressing dementia, a lessened capacity to reason correctly, greater impulsive tendencies, and often a more marked and more acute state of mental disorder.

The third class of cases are those in whom the mental development is up to the average and where the epilepsy occurs at a later period of life. Here there is great variation in the effect of the disease on the mind functions. As already stated, in a few cases it may exist for years with scarcely any untoward influence. Perhaps closely scrutinized, even in these there will be discovered slight impressions on the disposition of the patient. He is a little more querulous and impatient than formerly and slightly more emotional.

In the large majority of cases the mind functions suffer more decidedly. The destructive change is more marked. There is a gradual dementia, a very noticeable emotional tendency, marked irritability or a disposition to develop unjust suspicions of those about them. It has become almost proverbial with those familiar with such cases to remark on the disagreeable character of the change in disposition developed by the disease.

Epilepsy, which has its origin during the post-developmental period or in the latter years of adolescence, has none of the accompaniments of imbecility as described in those forms we have been considering. There is often a neurosis in the form of a suseeptible or unusually unstable nervous system, and this may have shown itself in other forms of nervous disease, such as chorea during childhood, night terrors, somnambulism, delirium from relatively slight causes and irregular convulsive attacks from reflex causes.

In other cases the epilepsy appears with very few or none of these previous manifestations and in persons with apparently stable nervous systems. The extent to which the disease, appearing at these periods of life, results in mental disorder or deterioration, and the character of this deterioration vary greatly in different individuals. There are a few epileptics throughout the country in whom the attacks are only occasional, where its origin is obscure, which sometimes, at least, can only be called idiopathic, where the mental deterioration is scarcely sufficient to be measurable. It may so exist for years, the individual discharging responsible duties in the meantime and with no perceptible change in disposition, or mental capacity, and with no disturbance of the mental equilibrium beyond the temporary unconsciousness of the epileptic attack. How large, or rather how small, a proportion these are of all the cases developing it is difficult to determine. In my opinion they are so few in number as to be considered exceptional. In a considerably larger number of cases so developing there is a general mental depreciation. Increasing

dementia, with more or less well-marked recurrences of periods of excitement, marks the progress of the damage to the brain as the epilepsy continues. These phenomena may be the accompaniment of any of the regular types of the disease, whether the attacks are chiefly of grand mal or petit mal or occur at night or during the day. The rapidity and extent of the mental deterioration does bear some relation to the frequency of the attacks, however, and also to their severity. There is a very strongly marked individuality in this disease as to the character of the mental changes produced by it. Sometimes these are very noticeable preceding, during and following the convulsive attacks, with slight disturbance at other times. In others the attacks are not accompanied by much exaggeration in the mind disorder, but it is constant and progressive at all times.

In the first of these classes, those showing no perceptible mental disorder, while the evidence of occasional epileptic attacks should cause a careful scrutiny of the probable motives resulting in criminal acts, it is exceedingly doubtful whether any great weight should be given to these as a relief from responsibility. The probabilities are that a study of any such case will disclose motives not different from those resulting in criminal acts in others and that the individual is only acting out his normal propensities. In my experience, if such persons were peaceable and law-abiding previous to the appearance of the disease, they continue so, and if possessed of criminal propensities, these are not especially affected by it.

In the other class, those which manifest mental disorder or depreciation, great conservatism should be used in maintaining responsibility before the law. In my view the presence of epilepsy should be held to still further diminish this responsibility over other cases with a like amount of mental depreciation and without the epileptic complication. This is because of its well-known tendency to explosions of violence, its disturbance of consciousness and its effect on the general disposition as displayed in the emotions.

By far the most difficult cases to locate in their medico-legal relations are those more or less irregular forms where the disease is not shown so much by regular convulsive attacks as by what are called psychic equivalents, masked or larvated attacks and periods of unconsciousness or unconscious or subconscious cerebration, without very evident implication of the muscular system. That such cases occur there is no doubt. That this form is more or less allied to true epilepsy I believe to be a fact. That cases of this nature may have very little evidence of mind disorder of a permanent character is also doubtless true. I think it very rarely happens, however, that we should be long at a loss to determine whether a given criminal, or apparently criminal act is or is not the product of such a condition. It is rarely if ever the case that acts in the unconscious state or of unconscious or subconscious cerebration are other than purposeless or such as have ordinary and innocent motives. They very rarely if ever have that method that leads to such criminal acts as would leave a doubt as to their criminal origin. Usually the absence of any adequate and reasonable motive and the incongruous nature of the act as compared with the known character of the individual are sufficient to indicate its origin in disease. It is very dangerous to the safety of the community to concede that such conditions may occur in cases of ordinary epilepsy and result in ordinary criminal acts in persons who might reasonably be supposed not to be above suspicion toward such propensities and in whom no other proof of unconscious states of like character is forthcoming. For instance, a few days ago a case was brought to my attention of a woman arrested for shop-lifting, who had had occasional attacks of epilepsy previously, but in whom the thefts were perpetrated with all the secretiveness and method and with the apparent purpose of the ordinary thief. A few months later she was discovered soliciting men for illicit sexual purpose for mercenary ends, in the ordinary way and in apparently full possession of her consciousness. In each case she pleaded entire unconsciousness of the act, and yet in each she was not above suspicion from formerly manifested characteristics. I can scarcely believe that unconscious states result in criminal acts under such circumstances.

It is true, however, that the presence of epilepsy has a tendency in some few instances to affect chiefly the moral qualities of the individual and to bring about a change in character more or less marked. The morbid character of this change is usually easily determined, however, by comparing the individual with himself at a period before the development of the disease.

Another problem, very difficult of solution in some cases, is to determine the influence of those periodical changes in emotional states that occur in epileptics which in no sense approach automatism and which are not accompanied by subsequent unconsciousness of the events occurring during them. It is well known that many epileptics vary greatly in their emotional states, and that this variation often has a relation to their convulsive attacks. During these periods of more or less emotional excitation the ordinary features of their environment affect them very differently from the influence they have at other times, and the degree of self-control of the patient is often very much lessened during these periods. Much consideration should be given to these variations in determining responsibility for criminal acts, and we will be aided greatly by a study of the history of the patient, for it is well known that while the peculiarities in the manifestation of these states are multitudinous in different cases, they incline to follow the same lines in the same case. If such emotional irritability exists in any instance, sufficient to be considered an excuse from responsibility for acts occurring during it, even when these have sufficient exciting motives, the history will disclose similar conditions previously.

The same is true of the influence of an actual psychic aura in causing apparently criminal acts. These auræ commonly follow certain lines and are prone to be repeated in like form in any given case. Proof ought scarcely ever to be wanting of such phenomena in the history of any case where there is a suspicion that a given act may be the product of such a condition, and in the presence of such auræ in the history of a case we should hesitate to insist on full responsibility.

TREATMENT.

DR. F. SAVARY PEARCE, Philadelphia—I believe thoroughly in antisepsis, intestinal antisepsis in particular, in cases of epilepsy. While we do not know the cause of epilepsy, as has well been said, we certainly do know that it is precipitated by intestinal autointoxication in many instances. I have seen cases in which constipation has undoubtedly been the cause of the patient having his attack of epilepsy. Hence in these epileptic states it is my practice to look to the intestinal tract and to at once administer some drug or other measure which will induce evacuation of the bowel and prevent the condition of constipation and autointoxication. First, then, the disease of the intestine, of course, must be looked into, and it goes without saying that mucous colitis, chronic gastritis and the like must be corrected. Papilloma of the intestine, while it can not be mastered very well, should be treated, if possible, for these growths may produce reflex epilepsy. Rectal irritation is another gastrointestinal symptom that should receive attention, and perhaps surgical correction of fistula in ano may have the effect of removing the cause of the attacks in a minority of symptomatic cases. All the antiseptic measures, such as lavage of the stomach and high enemata or flushing out of the colon, should be employed in these cases. I heartily approve of the use of salol in such patients. A full dose of castor oil occasionally is of value also to unload the bowel.

In reference to diet, I will only state that we should study the individual and see what is best suited as the diet of that particular person. I certainly believe that the proteids should not be withheld as much as they usually are, particularly in anemic patients. I am positive that I have seen patients benefited by the use of good beefsteak properly cooked. In those cases the use of iron would be of value. Predigestives, such as peptoids and the elixir of lactopeptin, are of value in correcting disturbance of the gastrointestinal tract.

Then the reflex causes, I repeat, should be looked to. I have seen a case in which I think phimosis in a boy, which was troubling him, was the cause of the epileptic exacerbations, and the removal of the prolonged prepuce aided in bettering his

condition. So with ovarian disease. So it would be with other reflex causes, such as from neuralgia or deafness. I have seen a woman in which I feel that the deafness was the cause of the epileptoid convulsions; she was getting on past middle life; so that progressive deafness, with sudden tinnitus and vertigo, it would seem to me to be more frequently seen as the exciting cause of epileptoid attacks than we give credit for. The ear should be carefully looked into in any case with vertigo. We all carefully look to the eyes of our patients for reflex causes, I think, and perhaps forget some of the other things that are just as important in producing an attack. Physical and mental work should be very carefully regulated. Certain it is that a great many patients pretend to, and their families try to have them, do the same amount of work that they have been accustomed to do before the development of the disease. The physician should insist on a suitable reduction in the amount of work, according to the state of the disease and the degree of the patient's resistance.

Now, in regard to the use of the bromids; while I use the bromids a great deal, the same as any other physician, I have seen so many untoward results following the administration of these remedies recently in dispensary practice that caution in their use has been indulged. All acnes develop from the excessive use of the bromids, and this is particularly true in regard to such patients as are the subjects of epilepsy who are in a feeble state of circulation. The physician is not always responsible for this, because the patients come to him and obtain a prescription; they get better and go on their way, very often continuing the use of this remedy for years. So that I think that it is important for the physician to urge on the epileptic patient, and especially on the family of the epileptic, that they should not continue the use of the bromids, except under the observation of the family physician. I certainly agree that solanum is a remedy of great value, and bleeding in the epileptic status I have seen do good. Eliminative measures, such as large draughts of water between meals, I have seen do great good. Hydrotherapy, such as hot baths and hot packs, frequently will aid when the patient is having a series of attacks. Elimination by the skin is thus added to bowel and bladder elimination. Castor oil, again I wish to urge, is one of the best drugs that we can use in the intestinal cases for its action on the toxins in the intestinal tract, over and above the cathartic action of the oil already indicated. This drug is therefore given with the idea of producing an antitoxic condition of the intestinal tract and thus neutralizing toxic products that are found there. Dilute nitro-hydrochloric acid is another drug of great value, especially when the patient is bilious. Then the diathesis of the patient must be looked into. If the patient has gout he must be treated for his gout. While I do not mean to say that the gout is the cause of the epilepsy, or that the uric acid diathesis is the cause of an epilepsy, yet these conditions are apt to introduce substances into the blood which cause malnutrition of the brain irritation. So in cases of traumatic epilepsy, the condition is bettered if the nutrition and general condition of the patient is improved.

The prognosis in these cases is very good, particularly if the patient is a child, and provided the treatment is faithfully carried out, especial attention being given to both hygienic and dietetic measures.

I would call your attention to digitalis (gtt. v to x) in combination with the bromids (gr. x to xv) t. i. d. I have seen cases in which the patient had not been getting along in which they did remarkably well on the bromids in association with the tincture of digitalis. It is especially valuable in cases where there is feeble circulation, with lividity of the skin. In some of these severe cases the use of 10 to 20 drops of the tincture of digitalis may have to be used in association with your bromids, and will often correct the difficulty, i. e., the poor circulation together with lessening the attacks. Thus combined with the bromids, then, I feel that digitalis is a valuable adjunct to the treatment of this condition of cardio-vascular weakness in the epileptic.

DR. T. D. CROTHERS, Hartford, Conn.—I wish to note a new treatment which appears to be valuable. A year ago I fitted up in my hospital a room with electric lights as an adjunct to the drug treatment. Some months ago an alcoholic epileptic was admitted and has been taking these electric-light baths twice a week ever since, with an entire cessation of the paroxysms and a marked improvement in every particular. Whether this improvement is temporary or permanent one can not say, but it is quite evident that the effect of the electric light on the body, with subsequent massage, has produced a change which is prominent. Has the electric light some specific power to produce a change in the organisms, or is it simply a depurative tonic? Whatever its action may be it is a powerful remedy beyond question or doubt. This patient had been afflicted with epilepsy for four or five years, and had a paroxysm every two or more days. Whether this was due to some constitutional condition or from drug-taking is unknown, but during the last six months there has been an entire cessation of the paroxysms. From the moment he took the first electric-light bath he has improved. This bath is made up of 100 16-candle power electric bulbs. Intense perspiration follows after from six to eight minutes of exposure, then a feeling of stimulation.

NOCTURNAL EPILEPSY.

DR. FRANK P. NORBURY, Jacksonville, Ill.—There has been very little said about nocturnal epilepsy, a condition in which I am greatly interested. I would like very much if some one more experienced than myself would discuss this special feature. For some years past it has been my misfortune, rather than my fortune, to meet a great many cases of nocturnal epilepsy, occurring especially in children during the school year, and more particularly during the latter part of the school year. I am frequently called on to see such cases in consultation. My experience, however, is not limited to children, for I have observed the same phenomena in adults; this past winter I saw two students, grown men, one from a conservatory of music, who only has an attack when under special stress. These attacks always occur at night. The other young man has on an average three a year. He is not himself aware of the occurrence of these attacks, but those near him know of them and report to me. It is especially noticeable that they occur the latter part of the school year. I have also under observation another case, that of a young man who has nocturnal epilepsy, but who is able to work every day; he probably may be off duty for a week out of the year. These attacks come on at irregular intervals; when they do occur he may have three or four attacks within a week. He is able to report for duty every morning. Another case is that of a dry-goods merchant, who in the town in which he lives is not known as epileptic; yet he has an attack on an average about once a week. These attacks do not interfere with his business capacity. Another case is that of a bank clerk, who during the past five or six years has had six or eight attacks of nocturnal epilepsy each year.

In none of these cases have I observed any mental impairment of any consequence. They are all of the same class and the patients are all markedly bright intellectually; the children stand foremost in their classes and are doing good work. This type of the disease seems to me to be a class of cases by itself, and not the ordinary depressing epileptic condition. The patients are all very bright and in good physical condition.

In the treatment of nocturnal epilepsy I have used biborate of sodium in conjunction with the bromids. In all cases I have insisted on thorough elimination by the bowels, using ordinary salts (sulphate of magnesium) daily in the morning before breakfast. This insures a thorough evacuation during the day, which I believe is successful in keeping away autointoxication from this source.

INSTITUTIONS.

DR. JAMES H. LLOYD, Philadelphia—We can only discuss from a very indistinct knowledge this whole subject of the pathology and the so-called pathogenesis of epilepsy. It seems to me that in the whole domain of pathology there is no condition which is so absolutely unknown as the pathogenesis of epilepsy. I do not wish to be pessimistic in discussing this subject, but I should like to call attention to one fact that has been brought out very prominently here to-day, and which I think is the most important thing that has been brought out

in this whole meeting, that, while we are in the dark and the prospects are that we are going to stay in the dark about the true pathology and the true histology and the true pathogenesis of epilepsy, and while we do not know what causes epilepsy, we can at least take care of the epileptic himself; and the paper which was presented here by Dr. Spratling to-day, giving us the details of the work which it is possible for us to do, was, to my mind, an exceedingly valuable one. Coming, as it does, from a man who is right in the midst of this work, that paper is educational. It ought to have great effect and influence in making every man in this Association, when he goes back to his own state, when he goes back to his own hospital, to make him an evangelist in this cause, in starting in every state, not one, but in close proximity to every one of the large cities, several institutions for the care of epileptics. I remember so well when I was at our Blockley Hospital in Philadelphia, the sight of our poor epileptics, sitting there doing nothing day after day, week after week, month after month; sitting there in absolute idleness; as we used sometimes to say, "sitting there doing nothing but waiting for the next fit." The next fit might come this afternoon or it might not come until next week or next month. After it was over it would be just the same thing; they would just simply sit there and wait. There could be nothing more demoralizing, and nothing more absolutely wretched, than the sight of these poor people sitting there with absolutely nothing to do, waiting for the next fit. It seemed to me this was the most forlorn sight in the whole hospital. I used to fear some of them would get fly-blown, sitting there without any occupation for either mind or body. And the degeneration which goes on in these epileptics is accentuated by this sort of idle life.

DR. C. H. HUGHES, St. Louis—I have heard no mention made of the epileptic floor, and I would like to suggest a suitable elastic rubber floor for epileptics. I recommended such a floor when I was superintendent of the Missouri State Hospital for Insane. We had about five hundred acres of ground and an epileptic colony then. Of course, we could not get all we wanted, but my plan was to construct a floor in such a way that the epileptic would be protected from falls. We should have the same regard for their condition that we have for the condition of other insane. We should not only protect them during their attacks, but also make the floors elastic and protect the heating apparatus, so that they may be guarded from the effects of such accidents belonging to epileptic seizures.

In regard to nocturnal epilepsy, I think it is the most difficult subject we have to treat. Suggestion has been made here in regard to the use of digitalis. My custom has been to use digitalis and strophanthus and other heart supporters for these patients, and I usually employ the bromid of ammonium instead of the bromids of sodium or potash for such cases. I take a more hopeful view of these epileptic cases than formerly. A large number of these patients have come to me for treatment since I left the Fulton Asylum. What we endeavor to do is to suppress the epilepsy. I expect some day to be able to publish some of my cases. A number of my cases of epilepsy have recovered, and I am not so pessimistic as some of the gentlemen on the subject of epileptic recoveries. The first case of epilepsy that I treated successfully was in 1859. I treated that case successfully with nitrate of silver, and that case has led me to the conviction that toxicity has something to do with exciting the paroxysm. Then there is an epileptic habit governing the neurons that produces proneness to attack of epilepsy, precipitated, I think, by autotoxicity. We should remember these two things in the treatment of epilepsy. Oppenheim has said that syphilis and civilization are the two essential factors in the production of paresis. I believe that the aptitude of the neuron, with the condition of toxicity, are the two essential factors that give us epileptic disease. I believe in the vasomotor theory of the production of the epileptic paroxysm. I believe in the theory of vasomotor spasm and alternate paralysis. I believe, so far as we can determine from the symptomatic condition, that nothing is better demonstrated.

DR. H. A. TOMLINSON, St. Peter, Minn.—According to the statements of some of the speakers we do not know anything about epilepsy, and if this belief is general any attempt on my part to answer Dr. Spratling's question would be futile. However, if I understand Dr. Spratling's point of view, he wants to make a distinction between the so-called psychic epileptic equivalent and what he considers to be a true epilepsy with only psychic manifestations. As stated in my paper, I do not believe in the so-called psychic equivalent. I believe that these states are not the equivalent of the convulsion, but that they are conditions of mental aberration following the disturbance in consciousness, which takes place as the result of an attack of petit mal, and which persists as a mental status.

As to whether there is such a condition as psychic epilepsy depends on the sense in which we use the term. Strictly speaking, I can not imagine a psychic seizure corresponding with the motor seizure. But if we accept the ordinary interpretation of the word epilepsy, I believe we must accept the existence of the condition referred to by Dr. Spratling, in which there is a state of suspension of consciousness with automatic conduct out of accord with the environment of the individual.

DR. W. P. SPRATLING, Sonyea, N. Y.—It is a question to my mind as to how far we should go in trying to differentiate between psychical epilepsy and the so-called psychical epileptic equivalent. Clinically they seem to me to be separate and distinct, while pathologically they probably spring from different parts of the brain. In all probability psychical epilepsy has its origin in the silent or intellectual areas of the brain, its chief peculiarity being that it does not produce muscular commotion of sufficient kind or degree ever to be at all noticeable. On the other hand, the psychical epileptic equivalent may begin in the same silent regions, but it quickly spreads to the motor areas, producing the wildest possible muscular commotion, general in character. If this is true, the two conditions are one and the same thing, differing in degree only, being local in effect in the former and general in the latter. One strong argument in favor of the seat of the discharge being mainly in the intellectual centers in psychical epilepsy is the fact that epileptics of this type oftenest and most severely suffer mental deterioration.

I am confident that the time will come when every state in the Union will have colonies or institutions suitably designed and constructed for the proper care of all grades of epileptics, for it has been amply demonstrated that the colony system of care and treatment is the system superior to all others for this terribly afflicted class.

DR. CHARLES K. MILLS, Philadelphia—I would like to emphasize what Dr. Lloyd has said. The colony method is the method of solving the problem of what to do with the epileptic. As is doubtless known to some of the members of this Section, I was engaged with others in the foundation of the epileptic colony which is located at Oakbourne, Pa. I would like to emphasize what has been said by Dr. Spratling in regard to the establishment of institutions for selected cases. Our Pennsylvania institution is not a state hospital; neither is it for selected cases. It probably comes between the two—the state hospital, which receives cases indiscriminately, and the hospital where cases of a selected kind only are taken. We have been fortunate in that several have given handsomely of their private means for its support.

TREATMENT.

Not much will be accomplished by electric light treatment that has been described. While epilepsy can scarcely be classed with the curable diseases, it is often relieved; the intervals between the paroxysms are often much extended, and what might be termed an approximate cure is effected. The hygienic conditions surrounding the patient should be regulated, and this can best be done on colony farms. The mental and physical habits of the individual should be regulated, and in addition he should be given certain drugs. Usually I employ certain drugs in connection with the bromids. One or two of these have already been mentioned; for instance, it has been my custom for some years past to use conium in conjunction with the bromids and arsenic. I use it either in the form of the juice fluid extract or in the form of coniin hydrobromate. Good results can also sometimes be obtained from the use of

digitalis, strophanthus and cactus in combination with bromids and other drugs. Cod liver oil and other nutrient remedies are also of much service.

DR. J. M. KENISTON, Middletown, Conn.—I would like to describe my experience with the treatment of status epilepticus, which is always an unfortunate and alarming occurrence. Over thirty years ago Kussmaul and Tenner advocated compression of the carotids from all severe seizures, whether singly or in groups. Without regard to the "congestion" theory of epilepsy, there are certainly cases which present long-continued congestion of the vessels of the heart, with marked pulsation in carotids, often visible at a distance of several feet. When this condition of increased blood pressure exists the convulsions are more severe and prolonged, and in such cases I have found great benefit from compression of the carotids against the transverse processes of the cervical vertebræ. The pressure is applied by the thumbs and may be relaxed at the end of two minutes and then resumed. I have successfully treated several cases of status in this way. In cases of status without marked pulsation in the carotids I have had good results from enemata of full doses of chloral, morphin and bromids repeated once or twice at intervals of one to two hours.

DR. WILLIAM H. WALLING, Philadelphia—Six cases successfully treated do not warrant me in saying that there is a cure for epilepsy. I have had good results with galvanism in such cases, passing three to five milliamperes directly through the head for ten to fifteen minutes every other day. The first case when he came to me was having attacks every two weeks; now he has not had an attack for two years. Another case was that of a woman, aged 40, who came to me at a time when she was having attacks every week or every two weeks. That was two years ago, and she has not had an attack since. In this case I used also suggestion with marked benefit.

DR. HAROLD N. MOYER, Chicago—We all recognize that underlying the epileptic constitution is a nutritional disturbance. Two years ago I had under my care an epileptic to whom I had given everything, just as we all do, without success. He was a dispensary patient, one of those for whom so little can be done, because you can not control their habits, and they can only eat what they can buy, and they think it better for their epilepsy to live on the diet that they can afford to buy than to starve to death on the diet that you recommend. I began giving this man glandular extracts. I wrote a prescription first for the suprarenal extract. Although he had been an epileptic for many years the attacks ceased after the administration of the first dose, and during the one and one-half years that have elapsed since there has been no attack. Acting on this experience I have given suprarenal extract, in 5-grain doses, three times a day, to about 25 patients, and three-fourths of them have been benefited. I can not give you any suggestions as to how you might say whether or not a given epileptic is likely to be benefited, but the results reached have been far ahead of any other drug that has come under my observation, and I am going to continue its use. There is a possibility that these glandular extracts may cure a number of cases. With the work of Dr. Ohlmacher on the involvement of the glandular system we are all familiar. The relation of the glandular and lymphatic system would lead one to believe that possibly in the glandular extracts we may have a remedy for a certain number of these cases. Like everything else in these cases, I don't know why it is, but it seems to me that nearly all the remedies benefit the first three or four cases that come to you, and the next dozen people do not seem to get any benefit. I do not know whether it is in the physician or in the patient, but it is generally a fact. Next year, after further study of these glandular extracts, I hope to present the subject again.

In the treatment of epileptic patients I have adopted the following plan: I make my private patients bring me a daily record of their condition; what they eat, how they sleep, bowel conditions, etc.; regarding their mental condition, whether they are irritable, whether they have been depressed and whether they have been troubled. On this daily record is based the treatment. Of those records I construct a chart, which is of the greatest aid in the treatment of epileptics, both in the clinic and in private practice. I just use an ordinary sheet of foolscap paper, turning it on the side and letting each of the lines represent a day of the month, then I draw transverse lines and allow one of these lines to represent a normal condition, then another the psychical state, and so on. By talking to the patients about these different classes of symptoms they begin to recognize the subdivisions themselves and are able to tell you that they have felt irritated, and also in what way their condition has differed from normal. There is no one thing that has helped my work so much as this simple scheme of charting.

DR. AUGUSTUS A. ESHNER, Philadelphia—I think that in accordance with current conceptions epilepsy is to be regarded as a paroxysmal disorder, with a predominance of motor manifestations of a convulsive character and a fairly well-defined symptomatology, recurring with varying frequency and in varying intensity. The convulsion is not the disease; nor does a single seizure necessarily establish the disease. There are other convulsive and paroxysmal disorders. The simplest conception of the underlying condition, it appears to me, is an unstable nervous system on the one hand and one or more of a large number of irritants on the other hand; so that the therapeutic problem that presents itself comprises on the one hand the correction, so far as possible, of the nervous instability, and this I take to be the more important of these two factors, and on the other hand the removal of any or all of the many and varied irritants that may be accessible.

In the papers but little distinction was made between the attacks of major and of minor epilepsy. It seems to me that such a distinction is most important. In my experience, which I take it concurs with the general experience, while one can, as a rule, diminish both the severity and the frequency of the attacks of major epilepsy with bromids, for instance, the same result can not as readily be brought with the minor attacks. In this connection I think it worth while again to emphasize the utility of digitalis in cases of petit mal; this has been referred to, but it seems to me that the matter is important enough to have attention directed to it again. In cases of major epilepsy also I have seen the conjoint administration of tincture of digitalis oftentimes subserve a most useful purpose when the bromids alone proved insufficient. In connection with the question of mixing the bromids, I think it is a matter of common experience that, after one has used for some time any of the drugs that are employed in the treatment of epilepsy the effect seems to diminish and some substitute or alternate becomes necessary, whether a sedative or an intestinal antiseptic or a vasomotor constrictor or dilator or what not. What I mean to say is, to first follow the law's demonstration that, in other words, almost any new remedy seems to have a distinct effect in inhibiting the attacks, at least temporary, and I believe that one may accomplish a useful purpose in a similar manner by alternating the bromids or by combining them. I have found that when a single bromid is no longer efficacious a combination of two or three or four bromids, even without increase in dosage, may subserve a useful purpose.

The cases of petit mal have, in my experience, been most resistant to treatment, as a rule not yielding to bromids. In some of these cases I have seen brilliant results from the administration of digitalis alone, without bromids or other sedative. I have heard no reference in the discussion to the use of chloretone, although it may have been made. In some cases that I have had the opportunity of observing it has seemed to yield good results. The dose preferably should not be large. I would prefer not to give any more than from one to three grains twice or thrice daily. In the case of a child recently under observation the attacks of petit mal, which were repeated many times in the day, at times more than a hundred being counted, subsided entirely for a time when the administration of this drug was begun. The attacks recurred in smaller number shortly afterward, but their frequency was much less than formerly. I have employed sodium biborate in a number of cases of epilepsy, particularly in alternation with the bromids, when these had to be suspended for one reason or another, and have been satisfied with the results. In cases

of nocturnal epilepsy I think it best to administer the bromid in a single large dose at night, instead of distributing the remedy over the day. A source of greatest anxiety is constituted by those patients in whom the attacks occur at long intervals and in whom therefore the seizures can not be anticipated. It is really a serious problem what to do with them, and it would seem that the best thing is to treat them symptomatically; to look after their general condition; to correct gastrointestinal derangement; to prevent or remove irritation from any and all sources. It is in this class of cases, among others, that the best results can be hoped for from institutional treatment, through which patients can be kept under careful observation, useful occupation be provided, and, so far as possible, the attacks anticipated and averted.

At the Infirmary for Nervous Diseases in Philadelphia there has been used for a long time a scheme for recording the number and the character of the attacks, not quite so elaborate as that Dr. Moyer has described, affording a ready means of noting the course of the disease. This consists simply of a chart, with a transverse line for each month in the year, and a series of vertical lines for the month. There is thus provided a square for every day of the year, and in any of these the number of major attacks are indicated by means of small crosses, and the number of minor attacks by means of small dots. Each epileptic is given such a chart, which he brings with him at successive visits. At the close of the year the patient receives a new chart and the old one is made a part of the permanent record of the case.

REPLIES OF THE ESSAYISTS.

DR. TOMLINSON—Before beginning the discussion of that part of the subject included in my paper, I would like to say something with regard to the attitude of those who first discussed the pathology of epilepsy. They were not only agnostic in their attitude toward the pathology of epilepsy, but also pessimistic with regard to its future. It is true, as stated by Gowers, that idiopathic epilepsy has no morbid anatomy nor histology, and from what we know of the disease, its origin and progress, none would be anticipated. But this fact does not deprive us of data on which to base reasonable and rational speculation as to what may be the true pathology of the disease. While it is true that there is no morphologic change in the cortical cells which is incident to epilepsy, it is equally certain that there is no evidence that the morphologic changes found postmortem in other forms of nervous disease are incident thereto. From what we know of the processes of degeneration, they are as likely to be the result. It seems to me that the conclusions from the study of these morbid changes are as much a matter of speculation and hypothesis in one case as in the other, and no better confirmation of this contention is needed than the history of the deductions made from the data of the morphology of nervous disease during the past ten years. So that if there is room for an agnostic attitude toward epilepsy particularly, there is equal room for such an attitude toward the pathology of nervous disease in general. Especially when we take into consideration the fact that every known form or kind of focal or systemic disease of the nervous system may be present in symptomatic form, without any more evidence of lesion than there is in epilepsy. Besides, we have the data supplied us by physiology and general pathology as a basis for our conclusions as to the morbid conditions which give rise to epilepsy and other convulsive disorders, so that they are not merely speculative.

With this general knowledge, supplemented by careful clinical observation of a large number of cases, it seems to me both reasonable and rational to consider that we have in epilepsy the manifestations of a tendency inherent in the individual which results from a defect which is chemical and physical, but not morphologic. Therefore, the unstable mass develops the tendency to respond excessively to slight stimuli, with the resultant explosive activity, usually extreme and followed by unconsciousness.

It does not seem to me difficult to understand why there is first the tonic and then the clonic convulsion in epilepsy. If you will carry out the simple experiment of holding the arm out straight and fully extended for an indefinite time, you will be able to appreciate why a convulsion occurs as it does. After a little time the muscles become tense, the tonus increases and the arm becomes rigid. Later the arm begins to tremble, the muscles twitch; and if the effort is persisted in, the twitching degenerates into a tremor, to be followed by complete relaxation. We have here examples of the tonic and clonic convulsion. The tonic contraction means irritation, the clonic commencing exhaustion. It does not seem to me that speculation of this kind, which is based on known facts in physiology, supplemented by what we know of the processes of development and dissolution, is futile in the study of epilepsy; and this is especially true when we come to consider the subject of treatment. For, after all, we are not treating the epilepsy, but the conditions which give rise to the epilepsy. In order to do this intelligently we must be able to appreciate the significance of these conditions, and the extent to which they are the result of defective development. It is because epilepsy has not been considered in this way that there have been so many vagaries in its treatment, and so much futile surgical interference with conditions which are essentially and necessarily hopeless from the beginning.

There is very little for me to say with regard to my part of the symposium, because my paper was not discussed. It is unfortunate that the terms used to express facts in science do not have the same significance to all who use them, and, in my experience, this laxity of definition is more marked in the terminology of psychiatry than in any other branch of medicine. This confusion is probably largely due to the fact that this terminology has been transferred from the language of metaphysics and the nomenclature is not used etymologically. So much depends on what we mean by the term epilepsy and what we understand by psychic. Then, too, a great deal of the criticism of that part of the symposium which dealt with the pathology of epilepsy, derived its force from the the fact that the speakers used the term pathology as if it was a synonym for morbid histology. In other words, they left us to infer that no disease had a pathology which did not present morphologic change in the structure of the organ apparently involved. The word pathology, properly speaking, means aberration or perversion of function. There may be structural degeneration or disintegration as a result, but it does not follow, if there is not apparent structural change, that there is no pathology.

My part in the symposium, of necessity, had to do almost entirely with deductions which were speculative, but this speculation is only the formulation in orderly sequence of the facts gained from clinical study, postmortem investigation and the comparison of these data with human facts in biology and physiology.

DR. SPRATLING—We have found *Solanum carolinense* (horse nettle berries) valuable in some cases. As with any new drug in the treatment of epilepsy, it is most important to study the case on an individual basis, for a drug that will do good in one will be actually harmful in another.

I believe the term epilepsy is too indiscriminately used; in fact, greatly overworked. Every convulsion is not epileptic, and it is my belief that the time will come when we will quit calling simple convulsions, due to reflex causes, epilepsy. I do not say that such cases may not in time create what we call habit epilepsy, but to my mind it is oftentimes not the genuine disease. I believe that the location, primarily, of genuine epilepsy is in the brain. Some physicians claim that epilepsy is caused by a derangement of the muscular apparatus of the eye, and proceed to cure the disease by clipping the offending muscle. Others claim that nasal adenoids act in the same way and that cures are effected by removing the foreign growths. I think we are still very far at sea in regard to knowing when the word epilepsy should be used. I don't think we should stigmatize people as being epileptics who simply have convulsions.

The causes of epilepsy come under two heads: heredity and stress; the former being similar or dissimilar. In a study of some 1,200 cases admitted to the Craig Colony we found similar heredity to have been the cause of the disease in 16 per cent. of all cases; that is, there was epilepsy in the parents in

these cases. Alcoholism, insanity and tuberculosis comprise the factors of dissimilar heredity; alcoholism in the parent being the cause in 15 per cent.; tuberculosis in 14 per cent., and insanity in 8 per cent. in males and 12 per cent. in females, giving a grand total of over 55 per cent. due to heredity. The causes that come under stress are almost legion and entirely too numerous to call up at this time.

We treat each patient, as far as possible, along four lines: medical, dietetic, surgical and moral, always endeavoring to individualize the treatment as far as possible, and you can never get good results in the treatment of this very obstinate malady until the individual is singled out and treated as well as the disease; and then all forms of treatment must be correct and carried out with the most scrupulous regard to details. Do not rely too much on the bromids; they have some value, it is true; they help some in some cases, but alone I do not believe they have the power to cure. Of late new remedies have come into use, such as bromipin and dormiol, that possess the good features of the bromid salts without any of their bad ones; bromipin, in our opinion, being especially valuable when given in the form of an emulsion.

I have but little to say about the surgical treatment of epilepsy. We have collected the records of scores of cases of operation on the brain, and in none of them have the beneficial effects been permanent. I recall the case of a woman, about 38 years of age, who had an impervious uterus up to the age of 37. She was operated on, the uterus and appendages removed, and she never had a convulsion afterward.

I believe that in every case of genuine epilepsy of any duration the mind is always affected. The institutional treatment of epilepsy is, to my mind, the most valuable method, because it is only by this method that you can absolutely control the patient in all his habits, and you have to do that if you get good results. We should have a record of every attack, with the date and hour that it occurred; of the character of the attack and whether it was followed by loss of consciousness or mental disturbance; how long each stage of the attack lasted, and the point of origin of the convulsions. Our records are complete. While we have not devised a diagram such as Dr. Moyer mentions, I want to speak a word in favor of the Doctor's system of keeping his records. I don't think we ought to be too pessimistic about the pathology of epilepsy. It is only during the past eight or ten years—a brief time in science—that we have been doing work in this direction, and I think there is a great field before us. We ought not to say that nothing can be done for epilepsy, for I know much good can be accomplished.

Dr. Tomlinson spoke about the "epileptic equivalent," and I think the whole thing might be summed up like this: the man who is an epileptic and is in a condition of automatism is not in a condition to receive new impressions; his mind is like a camera plate that has been exposed—it is dead to new impressions. He can only act on impressions, on knowledge previously acquired, but can not receive new ones. This condition is important from the standpoint of medical jurisprudence.

DR. J. H. MCBRIDE, Los Angeles, Cal.—Dr. Spratling said in the early part of his paper that about 8 per cent. of epileptics become insane. In another place I understood him to say that 16 per cent. of genuine epileptics became insane. It would seem, therefore, that much depends on what you include in the term genuine epilepsy. My own experience is that all habitual epileptics suffer some mental deterioration, and while not all of them can properly be called lunatics, neither ought they to be spoken of as sound in mind. We lay too much stress on the fit; the epileptic is usually in a morbid condition in the intervals of the fit.

DR. SPRATLING—I take it that in the first case the epilepsy was due to what we call a distal or reflex cause. The chances of cure in such cases are always better than when the cause is proximal or entirely within the brain. I did not say that 8 per cent. of all epileptics become insane, nor do I regard any epileptics as being perfectly sound in mind; and after that it is only a question of degree. Out of 1,200 cases studied at the Craig Colony 15 to 20 per cent. were found to be subjects for permanent hospital or asylum treatment, while a very much larger per cent. were feeble in mind to some degree.

SYPHILIS OF THE LARYNX.*

CHARLES M. ROBERTSON, A.M., M.D.
CHICAGO.

Syphilis of the larynx is the local manifestation in the larynx of constitutional lues. It is observed in all its different stages and may be either hereditary or acquired. It is classed as (*a*) the primary lesion, (*b*) the secondary, including the erythema, mucous patch and superficial ulcer, and (*c*) the tertiary, including the gumma, deep ulceration, perichondritis and stenosis. It is fortunately quite a rare manifestation in this disease, occurring in 2.9 per cent. of cases as observed by Lewin, 2.4 per cent. by Schrotter, 3.4 per cent. by McKenzie, 2.8 per cent. by Engelsted. These observations are not altogether unanimous, however, as some authors put the per cent. as high as 15. Its occurrence in the pharynx is given by these authors as 10 per cent., and in the nose as 2.8 per cent. The London Throat Hospital reports out of 10,000 cases of this disease, 308 affections of the larynx and 834 of the pharynx. Most of the cases cited were from 30 to 50 years of age. This is probably due to the fact that the individuals are more prone to infection after the age of 20 and seldom after the age of 50. Up to the present time but one instance of primary lesion has been observed, as stated in a case related by Moure,[1] in which he observed a chancre on the free edge of the epiglottis. When the disease is hereditary it occurs either in the early months of life or about adolescence. In the former we have the secondary and in the latter we encounter the tertiary manifestations of the disease.

SYMPTOMS.

There are mild cases who complain only of an inclination to clear the throat, and from this we have all grades of symptoms to severe dysphonia, aphonia or dyspnea, which latter may increase ultimately to such an extent as to require the performance of a tracheotomy. Cough may be present in the early stages, but rare in the latter ones. The vocal function is impaired, and while at the commencement of the attack it amounts only to hoarseness, later it may pass to complete aphonia. Swallowing becomes almost impossible and the absence of pain when not attempting to swallow is most characteristic. The stage of erythema may be confounded with catarrhal laryngitis unless we look for the secondary manifestations accompanying it and the absence of the great amount of pain characterizing the catarrhal laryngitis. Ordinary laryngitis should be considered suspicious, especially if red patches are found on the vocal cords and we are able to elicit a previous syphilitic history. The mucous patch usually occurs on the upper or lingual surface of the epiglottis, more rarely on the aryepiglottic folds or ventricular bands, in the shape of small, usually unilateral ulcerations, which are oval in shape, whitish or yellowish in color, surrounded by an angry red areola. They vary in size from 10 to 15 mm. in diameter. The edges are somewhat elevated, and if the secretion be wiped away the floor of the ulcer is found to be the seat of persistent granulations. It is distinguished from the ulceration of tubercle by being larger in size, unilateral, and surrounded by the areola, while the tubercular ulcers are usually bilateral, are white, with no areola and are from 1 to 3 mm. in diameter, and usually found on the laryngeal surface of the

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. W. T. Corlett, L. Duncan Bulkley and W. L. Baum.

1. "Lecons sur les Maladies du Larynx," Paris, 1890, p. 229.

epiglottis. The superficial ulcer may occur with the mucous patch, or it may appear at any time from the second to the seventh year after the primary lesion by the breaking down of a superficial gummatous infiltration. It is often known as a recurrent ulcerative laryngitis. The subjective symptoms vary as to the site of the ulcer, but neither this nor the mucous patch is found below the true cord.

The tertiary form of this disease is characterized by gumma, deep ulceration and cicatricial contraction. The gummatous infiltration is sometimes seen in the character of a smooth rounded tumor of a yellowish appearance, circumscribed, usually on the edge of the epiglottis, the aryepiglottic folds, the posterior wall of the larynx or the ventricular bands. It has also been observed below the true cord, when it is called subglottic. After a certain period varying in time this gumma breaks down into a deep ulceration, although cases are cited where the tumor has persisted for 20 months without ulceration. When ulceration commences we notice the center of the gumma begins to ulcerate first, the process extending to the periphera until all the gummatous infiltration has disappeared. The appearance of the infiltration is sudden and the ulceration is like rapid in progress.

If there be any doubt as to the diagnosis of the condition present, we can corroborate our opinion in a few days with the administration of large doses of iodids; for there is always a marked improvement after the beginning of this treatment, though it may be transitory. They are distinguished from cancerous growths by the latter being slow to grow and resistant to syphilitic treatment. The deep ulceration is a natural sequence to the gumma and should not be expected before five years after the initial lesion. It is probable that the gumma has broken down before the patient seeks relief, so the first thing we see is the well-developed ulceration. We have a certain amount of local pain, especially on attempting to swallow, a tenderness on pressure. We find abundant mucus secreted containing shreds of necrotic tissue and streaked with blood. Hemorrhage is sometimes so severe as to endanger life from the necrosis of vessel walls, and one or more cases of death have been reported from this cause. Edema is, in some instances, so marked as to interfere with respiration and tracheotomy may be necessary to save the life of the patient. The ulcer in order of frequency is found on the lingual surface of the epiglottis, the true cords, the ventricular bands and the arytenoid space.

When the ulceration occurs near a cartilage such, as for instance, the arytenoid, or cricoid, we have a perichondritis arising which may lead to destruction of the part. Thus Labbé[2] reports a case where the arytenoid of the left side became detached and was inspired, causing death by suffocation.

When the perichondrium becomes affected there is pain, tenderness on pressure, increased impairment of voice and dyspnea. When this process progresses we often find a sequestrum formed which gives rise to a permanent discharge, either into the larynx or to the outside of the neck through a sinus or direct. The sequestrum may lie embedded in the tissues for years, keeping up a discharge indefinitely, or it may apparently heal, to be renewed from time to time, being apparently a relapse or a renewed attack. This process gives rise to the last stage of the disease, stenosis.

After the sloughing has become complete or almost finished, we are confronted with the cicatricial stage, which is by far the most dangerous part of the diseased condition, owing to the great contraction and the danger of the parts being attached to each other, thus causing a closure of the passages. The epiglottis has an unhappy faculty of uniting with the aryepiglottic folds or the side of the pharynx and sometimes to the ventricular bands. The arytenoid articulations are liable to become stiffened or fixed by ankylosis, thus causing the cords to become fixed in their position, which may be in the median line or any other position. We often have a web of tissue formed between the cords, or the laryngeal structures become so distorted as to be hardly recognizable, so great is this process of contraction, and cases are on record where the larynx has been entirely obliterated. In this stage it often becomes necessary to perform tracheotomy, and while the immediate result of the operation is good, it must not be forgotten that these patients are required to wear the canula for the rest of their lives. In most cases the voice is completely and permanently lost. The diagnosis is mostly confused with tubercle and carcinoma.

Syphilis.	Carcinoma.	Tubercle.
Pain usually slight.	Pain constant, lancinating.	Pain severe on deglutition.
Attacks any portion of larynx and ulcerates very rapidly.	Attacks any portion of larynx and ulcerates more slowly than syphilis.	Favorite site is the interarytenoid space or the base of the arytenoid cartilages; ulcerates slowly.
Rarely seen in the stage of induration. First evidence usually a clear-cut, deep ulcer.	First appearance is that of a new growth occupying the laryngeal cavity; no clear-cut ulcer.	Usually the first appearances are small spots of induration which spread rapidly, followed by great edema.
Some induration around the ulcer, but usually very little edema.	The growth fills or encroaches on the laryngeal cavity.	Great edema of the arytenoids.
Ulcer extends deeply, often involving cartilage.	Growth extends in all directions, involving all tissues in its course.	Ulcer extends laterally, but not deeply.
Surface of ulcer covered with muco-purulent secretion and necrotic tissue.	Surface of growth covered by discharge.	Surface of ulcer covered with thick muco-purulent secretion and agglutinated mucus.
Mucous membrane hyperemic and injected.	Mucous membrane hyperemic.	Mucous membrane pale.
Laryngeal stenosis not common till cicatrization occurs.	Laryngeal stenosis common.	Laryngeal stenosis rarely occurs.
General health unimpaired.	Early in the disease no impairment of general health; later a marked cachexia.	Health impaired previous to laryngeal involvement.
Frequently evidences of syphilis in other tissues.	In primary laryngeal carcinoma no other involvement until later in the disease.	Previous and coincident pulmonary trouble common.
Rapidly improves under iodids.	Not influenced by iodids.	Not influenced by iodids.

In syphilis the development of the ulcer is acute, occupying only a few days; in phthisis its development is slow, generally after months of throat symptoms, while in cancer it usually occupies a few weeks in development and the ulcer is preceded by development of a growth and nearly always exhibits round excrescences on or around the ulcer. The ulcer is solitary, irregular in shape and 2 or 3 cm. in diameter. The accompanying table gives the main differences between these diseases.

TREATMENT.

The treatment of the disease is both general and local, and the same laws that apply to its treatment

2. Bull. de la Soc. Anat. de Paris, 1857, vol. xxxii, p. 210.

in other parts of the body are, of course, applicable here. We therefore push the dosage of iodids to their tolerance. If there be any tendency to iodid poisoning a combination with 5 or 10 grain doses of sodium bromid given with each dose will often prevent the rash appearing. It is well to start the iodid in 20-grain doses, increasing it 20 grains every two days, or as rapidly as possible till the tolerance is reached. We often experience patients who will be able to take very large doses who will not stand a smaller one. Thus it is possible to give doses from 100 to 150 grains three times daily. In combination with the iodid treatment we give inunctions of mercury, either in the shape of blue ointment or the oleate, and this is administered by rubbing a dram into different portions of the body daily, each rubbing being preceded and followed by a warm bath. After the fourth dose it is well to discontinue for a day or two on account of the liability of salivating our patient. If the gums are touched at all, which should be avoided. we can administer a few doses of potass. chlorate and use a mouth wash of the same. If it is thought best, tonics can be given with the iodids for the support of the patient and after the process of ulceration is passed we place the patient on a prolonged treatment of mercury, in the shape of the protoiodid or bichlorid, instructing him to continue its use indefinitely.

If the bowel is disturbed by the mercury, the addition of a small dose of opium may be added. A favorite prescription of mine is a combination of mercury, iron and phosphoric acid. This is an alterative tonic and will in no way disturb the patient.

The local treatment consists in keeping the ulcerations clean by the use of detergent lotions, followed by the free use of peroxid, applied on a cotton applicator and the cauterization of the ulcerated spots with a solution of iodin crystals in creosote (saturated solution), or the ulcer may be painted or touched with strong solutions, or the solid stick, of nitrate of silver. If the ulcer shows a tendency to spread fast it may be burned with the galvano-cautery. If we find the ulcer very deep or pieces of tissue loose, we should cut away, or curette the necrotic tissue.

After cicatrization has commenced it is hard to effect much in the way of treatment. Our object in this instance is to prevent as far as possible the occurrence of great stenosis which is so liable to occur, and to be ready at any time to perform tracheotomy, as the contraction may progress so far as to preclude respiration through the natural passage. After we have made a tracheotomy we may try to dilate the larynx with bougies and laryngeal dilators, but as yet we are unable to hold out much in the way of improvement by their use.

DISCUSSION.

DR. L. WEISS, New York—What little I have to say relates more to the palliative features. I had a case a few weeks ago of syphilitic laryngeal stenosis, and the pain the patient had in deglutition was something terrific. I had tried many local applications and finally I came across orthoform and an application of a 5 per cent. solution to the affected larynx acted wonderfully, so soothing that the patient for the next six hours could swallow almost without pain. Orthoform is not as poisonous as cocain so it works in a quite different way. Furthermore, I would emphasize local applications to the throat of unguentum hydrargy. I have used eucain and I found the pain little less, but it does not act as well as does orthoform to alleviate the difficulties of deglutition.

DR.. A. RAVOGLI, Cincinnati—A kind of syphilis of the pharynx to which I called attention a few years ago comes in form of round ulcers, sometimes isolated, sometimes multiple on the pharynx, with sharply-defined edges, and a yellow lardaceous bottom. I do not believe these ulcers have to be classified in the tertiary period of syphilis, but I believe they are only in the secondary period. The ulcers come in different parts of the pharynx, sometimes between the end of the pharynx and the beginning of the esophagus. These come on sometimes with an attack of fever, and with a great deal of pain. The patient claims he can not swallow, and on careful examination I have found one or two of these ulcers in the pharynx.

Fig. 1 (Article of Dr. Wallis).

They yield easily to the treatment, which must be general and local; they are healed up in a couple of weeks, and leave only a very superficial scar. I have at present a case in the hospital affected with this kind of ulcer, showing up about fifteen months after infection; this is located just back of the tonsils on the pharynx. The local treatment which gives me the best results has been washing the ulcer with dioxid of hydrogen, and covering the ulcer with iodoform two or three times a day. In ten or twelve days I have obtained the cicatrization of this peculiar kind of ulceration.

The pain a dentist causes is remembered longer than any suffering he may have prevented.—*Sat. Evening Post.*

WAX MODELS OF UNUSUAL TYPES OF SKIN DISEASES.*

J. FRANK WALLIS, M.D.

Instructor in Dermatology in the Philadelphia Polyclinic, and Dermatologist to the Southern Dispensary.

PHILADELPHIA.

Skin affections which deviate from the usual type afford the greatest interest for the dermatologist. These freaks are sooner or later recognized and, by the aid of the sensitized plate, become valuable records. Although the camera is a useful aid in registering these rare conditions, yet it can not always convey to the observer all

Figure 2.

the peculiar details of these exceptional lesions, nor can words sufficiently describe these anomalies.

The nearest approach to the ideal, and that which overcomes the deficiencies of the photograph, is the wax model. It is the truest means of illustrating the morphologic conditions, and with the assistance of pigment the natural colors displayed by the pathologic processes are imitated.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. W. T. Corlett, L. Duncan Bulkley and W. L. Baum.

The models here exhibited are part of a collection made by Dr. Schamberg and the writer from patients attending the Polyclinic Hospital and the Southern Dispensary, Philadelphia. Their descriptions follow:

No. 1 represents a case of dermographism. This phenomenon was evoked by the writing pressure made with the blunt point of an instrument. The patient was the subject of a

Figure 3.

spontaneous urticaria lasting over a considerable period of time.

No. 2 shows a cutaneous horn on the back of the hand of an aged woman. It has existed about two years. The location has been unfavorable to growth. The lesion when first observed was higher than at the time the impression was

Figure 4.

taken; this modification was the result of treatment. There is slight inflammation at the base due to constant irritation, and some induration suggestive of epitheliomatous change.

No. 3 is an unusual distribution of psoriasis in a little girl, showing a peculiar symmetrical patch involving the inner surface of both thighs and meeting over the pubic and lower abdominal region. The disease had a strong resemblance to a

chronic scaly eczema, and was differentiated therefrom only after close study of the reaction to various remedies and the presence of a psoriatic patch on the scalp.

No. 4 shows an acute granuloma of skin. At the time the impression was taken the disease had progressed four months. The first lesion occurred on the anterior surface of the right leg below the knee; three months later the posterior surface of the same leg, and the anterior aspect of the left leg above the ankle, became likewise affected. The disease began as ecthymatous pustules, but exhibited, after the rupture of the roof, a granulating mass, honey-combed in appearance and studded with numerous small openings exuding a greenish-yellow, slimy pus.

The disease progressed peripherally and in the older lesions displayed a disposition toward involution, but attacking the border with renewed energy. The epidermis was apparently not affected in the disease. The pathologic process undermined the superficial layer of the skin without materially involving it. At the time the case came under observation pustules were forming in the vicinity of the lesions which behaved in a similar manner, eventually coalescing with the older involvements. At the time last observed—one month ago—the process had extended to the greater part of the surface of both legs.

The principal subjective symptom was intense pain, interfering with the patient's sleep. The pain was greatly aggravated by ordinary applications of even moderate strength.

Stained smears suggested short threads or filaments. The cultures from exudate resembled the cultures of actinomycosis. The stained preparation presented branching mycelial filaments, and in old colonies these filaments interlaced until the structure could not be defined except by teasing the specimen. In young colonies the staining of the filaments was uniform, but in older colonies there was segmentation. These preparations resisted acid reagents. No clubs were found, but a suggestion of swelling at the end of filaments occurred. Inoculations are at present not completed.

DISCUSSION.

DR. W. S. GOTTHEIL, New York—Having done work of this kind myself, I am in a position to appreciate the very great amount of patience and skill that is required to make these models. Nothing in the way of a photograph or painting, and still less anything in the way of verbal description, can approach it as a means of recording skin lesions. It is not possible, however, for a practitioner to devote to it the time that is required; and until we have some one like Baretta of Paris here, it can only serve as an occasional means of record in the hands of younger and artistically inclined dermatologists. Years ago, when I made my models, I was invariably asked by some one when exhibiting them what they were worth. I always answered that it was a labor of love, and that hundreds of dollars would not pay me to make one. I am the more sorry to see that some of those here exhibited have been broken in transport, and would suggest that they are entirely too valuable to be carried about.

DR. WALLIS—It was largely through the suggestions of Dr. Schamberg and Dr. Gottheil that this work was undertaken. Dr. Gottheil is one of the pioneers in the work.

Iodin and Gangrene.—The *Indian Medical Record* tells of a patient whose fractured arm was treated by his physician and who was then sent to a hospital to rest for a few days. The hospital surgeon inspected him, insisted that gangrene had set in, and was about to begin an operation on him when the patient's physician arrived with the information that the signs of "gangrene" resulted from the iodin application he had made.

Resolution Against Physicians Bidding Against Each Other.—The following resolution was recently adopted by the Hillsborough (Fla.) County Medical Society: *Resolved*, That it is the sense of the Society that any member who accepts or continues to hold any already accepted contract, to the exclusion of any other physician or physicians, as physician to any society, company or association organized for the express purpose of securing the services of physicians for less than conventional fees, shall be considered guilty of unprofessional and unethical conduct.

GASTROJEJUNOSTOMY WITH THE McGRAW ELASTIC LIGATURE, FOR THE RELIEF OF GASTROPTOSIS.*

H. O. WALKER, M.D.
DETROIT.

If, as Meinert asserts, 90 per cent. of all women have gastroptosis, and knowing as we do the inefficiency of mechanical and medicinal treatment of this distressing malady in a great number of cases, one may be pardoned for presenting a method that offers features of benefit, whether it is mechanical, medicinal or surgical.

Surgically, little has been done, and that but recently, in the way of improvement of this condition. Gastroplication and gastrorrhaphy are the principal procedures, and have not been attended with very brilliant results, as they do not always relieve the chronic pyloric kinking, and although I may not be presenting anything new, yet, as far as I know, except by allusion, nothing has been presented along the lines that I offer. With this brief introduction I beg leave to make a somewhat detailed report of three cases in which a gastrojejunostomy was done for the relief of a chronic invalidism due to gastroptosis.

CASE 1.—Miss A., aged 24, music teacher, was sent to me by Dr. Henry, Northville, Mich., and admitted to Harper Hospital Oct. 21, 1901, with a previous history of having had a fall when 7 years of age, causing a left inguinal hernia. For the last ten years she has had a variety of abdominal disturbances referable to the pelvic region, accompanied with disturbances of the stomach, such as distress after eating, with eructations of large quantities of gas, occasional vomiting and chronic constipation. Within the last three years she has had attacks of pain in the right iliac region, and about three months ago had an attack that was quite severe, confining her to bed for about a week, accompanied with vomiting and elevation of temperature. This point has been quite sensitive ever since. She has had a chronic leucorrheal discharge for several years, also hemorrhoids, and a sensitive left ovary. In fact, she has been in a state of chronic invalidism for years.

Examination.—A reducible left inguinal hernia was quite in evidence. A sensitive appendiceal area, a retroverted uterus, with chronic endometritis, internal hemorrhoids and a prolapsed, sensitive, cystic ovary were found. These conditions in themselves were sufficient to produce stomach trouble, so that as careful examination as should have been made of the stomach conditions was not done.

First Operation.—Oct. 22, 1901, after due preparation, I first did a curettement; then a herniotomy, following with a median section, removing the cystic ovary and the appendix, which showed evidences of chronic infection, and, lastly, the removal of the hemorrhoids. The temperature never exceeded 100, and after three days it dropped to normal, and she made a good recovery from these operations.

Subsequent History.—Her stomach trouble, however, did not improve, and a more careful examination was made, which, with the symptomatology, showed irregular attacks of distention, gastralgia, eructations, nausea and vomiting, with the persistent, typical constipation of gastroptosis. Palpation and percussion gave a succussion or swashing sound of a large quantity of fluid in the stomach, and its lower border could be mapped out below the umbilicus. At times considerable pain was referable to the gall-bladder area. There had, however, never been any jaundice; right nephroptosis was slight, stomach analysis, after a test breakfast, showed total acidity of .35 per cent., mostly lactic acid, with free HCl .12775 per cent.; undigested starch granules and a large amount of mucus.

Second Operation.—After explaining to her the advisability of another operation, she consented, and after due preparation I operated Nov. 29, 1901, opening the abdomen from just

---

* Read at the twenty-eighth annual meeting of the Mississippi Valley Medical Association, held at Kansas City, Oct. 15-17, 1902.

below the ensiform tip down to about five inches. No evidences of gall-bladder adhesions, constriction or thickening of the pylorus were apparent. The lower border of the stomach extended about two inches below the umbilicus, so that the pancreas was observable above the lesser curvature of the stomach as she lay on the table. On drawing out the stomach the transverse colon was down below that point, as well as a general enteroptosis.

My experience in gastroplication and gastrorrhaphy, in the few cases on which I have operated, has been far from satisfactory, and I conceived the idea that a direct opening from the stomach into the intestine would be better than an attempt to relieve the pyloric kinking by lessening the size of the stomach, or fixing it high up to the abdominal wall inside. I therefore concluded to

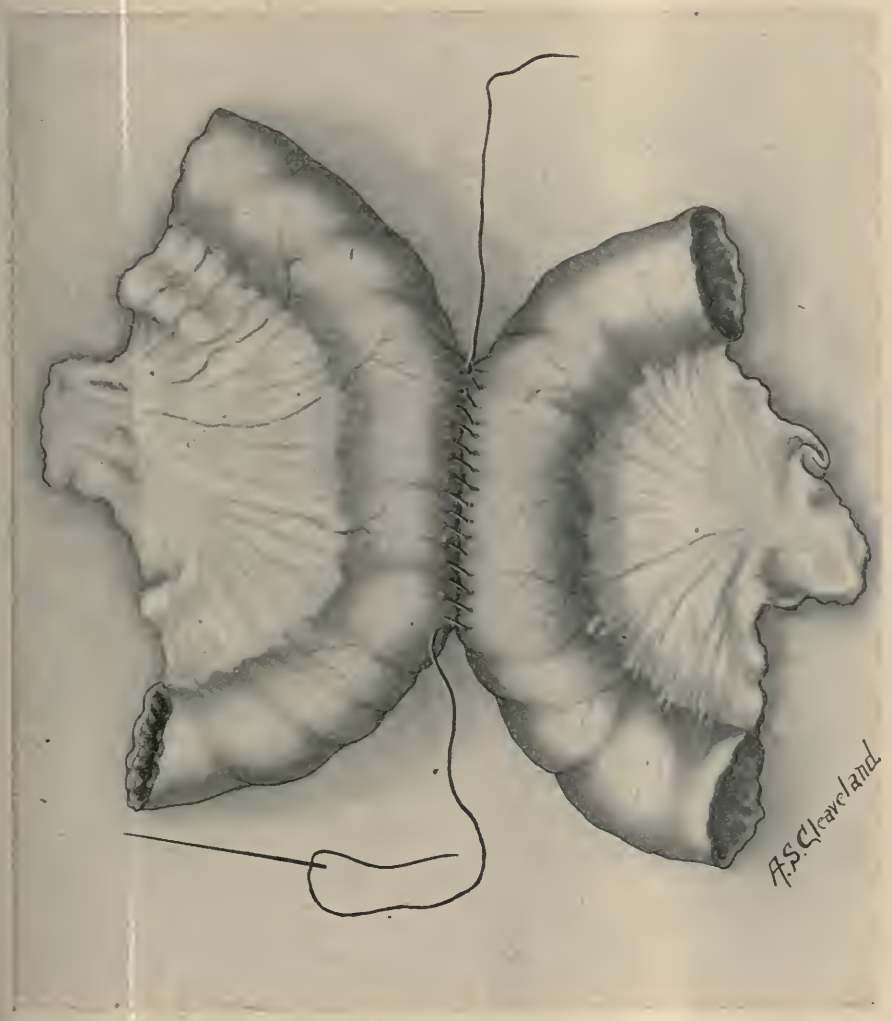

Fig. 1.—Approximation of serosa with continuous silk suture.

do a gastrojejunostomy by using the McGraw elastic ligature, in which the various steps of the method are shown in the illustrations that I herewith present.

Fig. 1 shows the approximation of the serosa by continuous silk suture. Fig. 2 shows the elastic ligature introduced. Fig. 3 shows one tie of the elastic ligature, with strong silk ligature underneath, ready to fasten the elastic ligature when it is drawn taut. As a matter of safety, before cutting off the ligatures, it is well to make another tie of each ligature. Fig. 4 shows the ligature tied; while Fig. 5 shows the operation complete with a continuous suture of the serosa entirely covering the knot. It is my custom in introducing the needle to take up full two and a half inches in the bite of both the stomach and intestines, thereby giving a large anastomotic opening.

This method was followed with this patient. I fed her mostly by the rectum for five days with beef and saline enemata every four hours, with occasional sips of water by the mouth. From this time on she was gradually fed by the mouth, taking solid food on the eleventh day. Her recovery was complete from the operation, and she left the hospital on the twenty-third day thereafter. I have seen and heard from her several times since, and she informs me that she rarely knows that she has a stomach.

CASE 2.—Miss M. P., aged 28, gives a family history of her father dying at the age of 48 from an accident; mother died at 33 after a long history of ill health. Her brothers and sisters, seven in number, are in good health. She has done housework ever since she was 14. At 6 she fell into a well, sustaining severe injuries, from which she apparently made a good recovery. At 15 she had facial paralysis; malarial fever twice, at the ages of 17 and 19, and a broken ankle at 20. In 1893 she had had her first attack of appendicitis, which was followed by recurrent attacks, when, in March, 1897, she was operated on during a severe attack, and the appendix removed, followed by recovery from the operation. Since 1890 she has had attacks of what she called indigestion or dyspepsia, with gas eructations, and pain referable to the liver and stomach, with more or less bloating. Her menstrual periods have been more or less painful. In 1898 she had what her physicians called nervous prostration, followed by acute articular rheumatism.

Examination.—In February, 1901, she consulted me for the first time since I had operated on her for appendicitis for pain over the region of the stomach and gall bladder, which had become unbearable, whether she had eaten moderately or not. She wondered whether an operation might be of benefit to her, and she expressed her willingness to undergo one if she could get relief. At this time her weight was much below normal. She had an anxious expression and was somewhat jaundiced. This jaundiced appearance had been noticed at intervals for some time. She had become habitually constipated; her tongue was coated, and there was constant eructation of gas. Inspection showed general tympany of abdomen, while palpation evinced pain referable to the stomach, but more particularly to the gall bladder. Percussion revealed a succussion sound over the region of the stomach extending to nearly the umbilicus. While it was apparent that she had gastroptosis, yet the preponderance of opinion was in favor of a gall-bladder lesion, in all probability calculi, with adhesions from previous attacks of cholecystitis.

First Operation.—Feb. 7, 1901, I operated on her, making a median incision, and the only lesion, aside from gastroptosis, that could be observed was a band extending from the gall bladder to the pyloric end of the stomach. This was relieved. The stomach could be readily brought out through the abdominal opening, and the lower border of the stomach extended below the umbilicus. Gastrectasia was not well marked, neither was there any thickening or apparent constriction of the pyloric orifice. Gastroplication did not seem to be indicated in this case, so I attempted fixation of the lower curvature of the stomach with several interrupted sutures to the ab-

dominal parietes on a line about two inches below the ensiform cartilage.

Subsequent History.—There were no untoward symptoms following the operation, and she seemed better for a while, but soon her condition became gradually worse, and continued so for more than a year, when she came to me again. I sent her to the Harper Hospital, with a view to attempting further surgical effort for her relief. At this time her pulse was 100, temperature 99, respirations normal, except for a slight bronchial irritation; appetite poor; bowels acting every day, with an occasional diarrhea; pain, especially when lying down, with nausea. She is very nervous.

On April 11, 1902, she was given a test breakfast, which was withdrawn one hour later; amount, 180 c.c.; reaction acid; undigested food from the previous meal; some mucus; total acidity, 0.225 per cent.; free HCl none. Lactic acid present.

Second Operation.—April 12 an incision was made in the same line as before. The previous fixation was satisfactory, except that it failed to accomplish the object for which it was intended, for the upper part of the stomach had rolled down and behind, making matters worse than before. I found (a statement which I neglected to make at the previous operation) a ptosis both of the liver and right kidney, together with general enteroptosis, which, however, was not marked. I first peeled off the attachments that I had previously made, so as to cause a perfect freeing of the stomach, then did an anterior gastrojejunostomy with the McGraw elastic ligature after the manner indicated in the report of Case 1.

Subsequent History.—The first three weeks of convalescence were satisfactory, as she did not complain of any of the old symptoms, but in the fourth week she began vomiting, which was preceded by pain in the back and right side, with an obstinate constipation. Vomiting became frequent and distressing. The symptoms pointed to partial intestinal obstruction or possibly a vicious circle, yet she did not vomit bile, but what seemed to be merely stomach contents from what she had eaten and drunk. The obstruction appeared rather to the left and above the point of anastomosis, or I could map out here an irregular intestinal outline.

Third Operation.—May 30, 1902, her abdomen was again opened, and extensive adhesions liberated. The intestine had assumed a horseshoe shape, and had become adherent on itself. The adhesions were freely relieved, and after satisfactory hemostasis I powdered the whole surface with aristol, as recommended by Morris, with a view of preventing their recurrence.

Subsequent History.—There was no vomiting for two weeks, when the situation became as before, with a return of the obstinate constipation, calling for vigorous catharsis and copious enemata. The abdominal distention and pain were unbearable, necessitating hypodermics of morphin.

Fourth Operation.—Having observed the reports by my friend Morris and others of the value of the Cargile membrane in preventing adhesions, I made another effort, July 26, to relieve her by using nearly a whole package containing twelve sheets of the membrane.

Subsequent History.—The adhesions were more marked than at the last operation, and after two weeks of comparative comfort the symptoms returned, with greater severity than before. Feeling through my efforts to relieve my patient that I had probably made her worse than she would have been, I felt that she demanded at my hands a further effort.

Fifth Operation.—So, on Aug. 29, 1902, I did what probably should have been done before, namely, made an enterostomy, using the McGraw ligature for the purpose. The point of anastomosis was made between the intestine, about eight inches below the gastrojejunostomy. It goes without saying that the adhesions were more extensive than at any previous time. The Cargile membrane had not been absorbed, but was firmly embedded in the cicatricial adhesions. I then, again, made a liberal peeling of all adhesions, and after causing hemostasis as much as possible, I filled the abdominal cavity to distention with normal salt solution, closing the abdominal wound with interrupted silkworm-gut sutures.

Fig. 2.—Elastic ligature introduced.

The Cure.—September 1 the vomiting had entirely ceased, and has not recurred. She eats anything and everything without any discomfort; she has daily natural evacuations of the bowels; in fact, she did not have an untoward symptom, and on Oct. 7, 1902, she called to see me at my office, presenting a perfect picture of health, to bid me good-bye, as she was about to leave for her home in Ontario.

CASE 3.—Mrs. K., aged 42, was brought to me by Dr. C. F. McDonald of Goodrich, Mich., with a history as follows, which he kindly furnished:

She was married twice, at the ages of 15 and 30 respectively, and was never pregnant. Her condition of health previous to four years ago was fairly good, except at irregular intervals. For eight years preceding 1898 she had distress in the region of the gall bladder and over the stomach. In 1898 these symptoms increased, pain radiating from the

ensiform cartilage in front to the right of the scapula behind and through the thorax. The pain was very severe and accompanied by chilly sensations, nausea, eventuating in vomiting, which was followed by immediate relief for a time. The vomitus consisted mostly of mucus and of whatever food was in the stomach, with bile at times. During these attacks there was never any elevation of temperature or undue circulatory disturbance. With these so-called attacks of indigestion there would be sometimes slight icterus and mental depression. One of these attacks lasted six weeks, followed with marked loss of flesh and strength. Following this severe attack she was fairly comfortable for nearly two years, although rarely a week passed without a reminder by uneasy stomachic sensations. About a year ago she had an attack that was more severe and prolonged than that of 1898. The interval symptoms continued until six weeks ago, when she had another severe attack. Medication and change of climate availed nothing. Dr. McDonald recommended an operation, with the expectation of finding gall-bladder trouble. Certainly the history pointed in that direction, yet with past experience I could easily make out gastroptosis, with characteristic swashing sound on palpation. In this instance no examination of the stomach contents was made, owing to a misunderstanding of instructions for preparations.

Operation.—The history of a gall-bladder lesion was so plain that I could not question its existence, yet on opening the abdomen there was no evidence whatever that it had ever been affected. The sagging of the stomach was very marked, for on withdrawing it and placing it on hot towels on the abdominal wall it easily extended to three inches below the umbilicus. The pyloric orifice was slightly lessened in size and thickened, due entirely to its long-continued kinking caused by the dragging of the stomach. There was ptosis of the liver, right kidney, colon and intestines generally. April 23, 1902, at the Harper Hospital, I did a gastrojejunostomy with the McGraw elastic ligature, in the manner heretofore described. This woman made a rather phenomenal recovery, in that she left the hospital on the fourteenth day after the operation. Dr. McDonald states that since her return home she has had none of the old symptoms; she has increased in weight, and appears perfectly well.

It must be apparent, except possibly in Case 2, where the band of adhesions was found, that the gall-bladder symptoms in all of these cases can only be ascribed to the dragging weight of the fluid-distended stomach.

Fig. 3.—One tie of the elastic ligature with a strong silk ligature underneath ready to fasten the elastic ligature where it is drawn taut.

In making gastrojejunostomy I resort to the anterior method, selecting a point in the intestine for attachment to the stomach fully twenty-four inches from the pyloric orifice, there being less possibility at this distance of causing a vicious circle. The symptoms of obstruction that occurred in Case 2 were entirely due to adhesions of the intestine to the anterior abdominal wall, and not a true vicious circle; yet as a means of prevention of this possible contingency it would be well to do an anastomotic enterectomy six or eight inches below the gastrojejunostomy. This was done in my last case, which I operated on three or four days before I left home, and the outcome of the operation I have not yet learned.

Of all the methods that have been suggested for the performance of lateral intestinal anastomosis, with most of which I have had a liberal experience, none, to my mind, possesses the advantages of the McGraw elastic ligature.

1. Its simplicity, which is far greater than any other method yet presented.
2. Ease and rapidity with which it can be done.
3. Less liability to sepsis than by any other method.
4. No danger of a foreign body.
5. A larger opening can be made without liability to cicatricial contraction.

In Case 2, where I had the opportunity of opening the abdomen three times after the gastrojejunostomy, I found the opening very large, with no tendency whatever to contraction. Although my experience with gastrojejunostomy for the relief of the distressing symptoms of gastroptosis is limited, yet the results thus far obtained are certainly encouraging enough to warrant further effort in this direction.

Orthoform in Differentiation of Painful Gastric Affections.—Orthoform has no effect on sound epithelium. Consequently, when it is taken into the stomach, if the epithelium lining is intact, it will have no analgesic action and the pains will continue as before. But if there is an ulcer or ulcerating cancer, the orthoform makes its action soon felt in the reduction of the pains.—Quoted in *Gaz. Med. Belge.*

THE MORTALITY FOLLOWING OPERATIONS FOR PUS IN THE PELVIS.

HUNTER ROBB, M.D.

Professor of Gynecology, Western Reserve University, and Gynecologist-in-Chief to the Lakeside Hospital.

CLEVELAND, OHIO.

In the course of his everyday reading, as well as in his own operative work, the busy surgeon is always meeting with new data, so that at the end of a certain time he finds his mind loaded up with a mass of undigested knowledge, much of which is of no practical utility, or even apparently contradictory. Under these circumstances he finds it necessary to pass in review from time to time all these accumulated ideas, and to sift out the chaff from the wheat so that he can once more start with a clear field and find himself in a position to answer the questions: 1. What have I learned lately which I can utilize in improving my surgical judgment? 2. What omissions from or additions to my operative technic will give me better results in the future? Probably the most satisfactory way by which he can attain this end is to make a careful classification of all his cases and as soon as he finds himself in possession of a sufficiently comprehensive series exemplifying a given pathologic condition to make a careful analysis of all the cases, and from the various data thus obtained to draw any conclusions that seem to be warranted, discarding what has proved to be worthless, and reserving for further consideration any points which may still be doubtful. It goes without saying that deductions based on a few isolated cases would be worse than useless and might be altogether misleading, and that the series should present instances of approximately all the various complications which may be met with in this particular class of operative cases.

During the past three years we have had in our clinic two series of unselected abdominal sections without a death. In the first there were 114 and in the second 108 cases. In the two together we encountered practically all the usual forms of pelvic lesions that occur in the female generative organs. From these cases, together with some prior and other subsequent instances, we have been able to make up a series of 100 consecutive abdominal operations for pus in the pelvis with two deaths. An analytical report of 72 of these cases has already appeared in a paper read before the American Gynecological Society in Chicago, May 30, 1901. Since the date of this publication we have had 28 additional instances. To-day I will briefly consider some of the bacteriologic questions connected with such pus cases, together with some points in the operative technic.

So far as I can gather from my reading, many surgeons would appear to still hold to the belief that the finding of pus in the Fallopian tubes and ovaries in a given case affords sufficient ground for assuming that the patient's chances of recovery following radical operative procedures are necessarily bad. So gloomy a prognosis, I feel sure, when based on the presence of pus *per se*, is by no means always warranted, and the general condition of the patient, as well as her capacity or inability to react after the shock of a severe surgical operation, are often of paramount importance. This is liable to be the case more particularly when dense adhesions have to be separated. Again, when pus is already present, not a few operators appear to assume that the carrying out of an aseptic technic, so far as they themselves are concerned, becomes no longer necessary, and when a fatal result follows an operation under these conditions or when the abdominal wound subsequently becomes infected, they are too apt to content themselves with the explanation that infective material was already present and its spread was only a natural result. Against such conclusions, however, we have the evidence of repeated bacteriologic examinations to prove that the pus found under such circumstances seldom contains living organisms. This observation has been demonstrated in my clinic in a large number of instances, in which no growths were obtained on the culture media, and the fact that the micro-organisms are dead undoubtedly plays a large part in contributing to the favorable results which often follow operative procedures. There is another point of interest connected with the treatment

Fig. 4.—Ligature tied. (Article of Dr. Walker.)

advisable in these cases, namely, the influence of the employment of palliative measures to the acute stages of purulent invasions of the Fallopian tubes and ovaries. I have long been convinced that it is an unwise routine to proceed at once to radical steps during an acute attack of pelvic abscess. Even if the patient does not improve somewhat in a short time under general hygienic measures and external applications together with the exhibition of suitable drugs, by simply opening up the cul-de-sac, in the great majority of instances the pus can be given an outlet through this channel, and the absorption of the toxic substances present in the pelvis can be diminished so that as a result the patient's condition will generally become better. She will then be able to withstand the shock if it should later become necessary to institute radical abdominal measures for the removal of the pus-sac contents. After having tried this plan of treatment in a considerable number of cases, and comparing the results with those following immediate radical operative procedures during the acute stage of pelvic abscess, I have become convinced of the great advantages of the former method in the majority of instances.

Fig. 5.—Operation complete, continuous suture entirely covering knot. (Article of Dr. Walker.)

The micro-organisms that are most frequently met with in cases of suppurative disease of the Fallopian tubes and ovaries are *Staphylococcus pyogenes aureus, Streptococcus pyogenes, Gonococcus* and *B. coli.* Other forms are occasionally met with, such as *B. tuberculosis,*[1] *Proteus zenkeri.* Of these organisms the one which is the most to be feared is undoubtedly *Streptococcus pyogenes.* But although its presence always makes the prognosis grave, it must be borne in mind that there are many instances on record in which this organism has been found during abdominal operations, and yet the patient has recovered. This favorable outcome is to be explained by the wide range of virulence possessed by *Streptococcus pyogenes.* In my experience a fatal peritonitis has sometimes followed operative procedures in which there were no macroscopic evidences of pus at the time of the operation, and I am inclined to believe that in such cases, with adherent lateral structures, the prognosis is often worse than when a considerable quantity of pus is met with. For this reason, and also because one can never be absolutely sure that the organism may not be very virulent, I have for a long time followed the rule of not performing more than one abdominal section on the same day, preferring to have more frequent sessions rather than to run risks. Whenever I find pus I always postpone carrying out any further abdominal work, except in emergencies, until 48 hours have elapsed.

Drainage.—The question of drainage in pus cases is always of great interest, and all operators are by no means in agreement as to its advantages and disadvantages. In my clinic we have not used a drainage tube during the past seven years, and we now, even in pus cases, seldom drain through the abdominal incision. When should we and when should we not carry out drainage in pus operations? As has already been suggested, the pus that is found in the Fallopian tube and ovary is in the great majority of instances sterile, and if this is the case, what advantage is to be obtained by the use of drainage? Again, if the pus encountered in a given case contains virulent organisms, will the use of drainage prevent a spread of the infection after a complete operation? After a thorough trial of both procedures, I have been forced to the conclusion that no form of drainage will prevent the occurrence of a certain amount of peritonitis if the organism present is virulent. There is, however, a class of cases in which drainage may possibly be indicated, namely, those in which it has been impossible to remove the adherent pus sac or structures completely. In these instances we employ for the purpose gauze sponges, which are introduced through the abdominal incision and carried out through the vagina. If the operation has lasted for a considerable length of time and the patient has been in a more or less marked condition of chronic sepsis, the drainage is kept up for from 24 to 48 hours. I must say, however, that

1. Recently my assistant, Dr. Howard H. Dittrick, has been able to grow the tubercle bacillus from the pus of a tuberculous salpingitis.

I do not feel altogether sure that even under these circumstances the procedure is always absolutely called for.

In passing, I might say that the only other cases which in my judgment call for drainage are those in which it has been impossible to control the bleeding that occurs after the separation of dense adhesions, or in which, during the separation of adhesions, a rupture of the bowel has taken place, and it has been an exceedingly difficult case to close the rent. In the former case the gauze is used more for the purpose of compression, while in the latter it serves to protect the bowel, and should a leakage of the contents take place they can find an avenue of escape by means of the opening made in the cul-de-sac through which the distal end of the gauze sponge is carried into the vagina. On the other hand, if we have not drained and symptoms should arise after an abdominal section, as the result of the absorption of septic material that has been introduced at the time of the operation, or from remnants of the retained diseased foci, we have plenty of time, as a rule, to reopen the abdomen and wash it out again, and then, if necessary, institute drainage in order to prevent the absorption of more septic material. Such cases are, however, fortunately very rare, and if we employ drainage as a routine in order to anticipate such a condition we may run many risks of infecting the patient.

THE TECHNIC TO BE EMPLOYED IN PUS OPERATIONS.

The technic to be carried out in operations for pus in the pelvis differs somewhat from that carried out in ordinary abdominal operations, and although the pus met with under these circumstances is, as a rule, sterile, practical experience has shown it to be a wise precaution to protect as far as possible from infection the portions of the pelvic contents which are apparently intact. In order, therefore, to limit the free distribution of noxious material throughout the abdominal cavity, it is our practice, as soon as the abdomen has been opened, to place large gauze sponges high up in the flanks on either side. If during our manipulations a pus sac is ruptured, we at once lower the patient and then make coverslips of the escaped pus, and, while these are being examined by an assistant, we try to remove as much as possible by mopping it up with gauze sponges. The pelvic cavity is then irrigated with large quantities of sterile salt solution in order to get rid of the greater part of the septic material and to dilute thoroughly any that may still be left. The enucleated mass is now surrounded with gauze which has been moistened in a solution of 1-1000 warm bichlorid of mercury. This gauze is not removed, if it can possibly be kept in place, until the structures have been cut away. If we unexpectedly encounter a pus sac before we have had an opportunity of applying our gauze protection pads, and if the contents escape into the pelvic cavity, the patient is at once lowered to the horizontal posture, and the pelvic and abdominal cavities are irrigated with hot sterile salt solution. The excess having been sponged out and the gauze protection pads placed in position, we then proceed with the enucleation of the mass. The pedicle is thoroughly cauterized with the Paquelin cautery, the abdomen is again washed out with salt solution and sponged dry, after which 300 to 500 c.c. of warm sterile salt solution are introduced and left in the cavity. The incision is closed without drainage. For 24 hours following the operation the lower end of the bed is elevated.

The situation of the pus in this series of 100 cases, the number of cases in which we were able to demonstrate organisms, and the classification of these organisms may be of some interest.

The pus was found as follows: In the ovary, unilaterally, 30 times; bilaterally, 6 times, including tuberculous cases. In the tube, unilaterally, 36 times; bilaterally, 52 times, with the tuberculous cases. In the appendix once. In the walls of the uterus, once. In almost every case in which the pus was unilateral the tube and ovary on the other side were found to be adherent. Infection of the tube and ovary together (tuboovarian abscess) was noted, unilaterally, 21 times, and bilaterally twice. The tubes were more liable to a bilateral infection; the ovaries, to a unilateral infection.

In the tubes and ovaries the following organisms were found: *Staphylococcus pyogenes aureus,* 3 cases; *Staphylococcus pyogenes albus,* 3 cases; *B. coli communis,* 4 cases; *Streptococcus pyogenes,* 4 cases; *Friedländer's bacillus,* 2 cases; *B. tuberculosis,* 2 cases; *Gonococcus,* 8 times positive (six others probable). Thus in 24 cases (24 per cent.) organisms were found.

We were not able to cultivate the gonococcus, except in one instance, and the diagnosis was made in the other cases entirely from the coverslip examinations of sections made from the tissues.

In the two cases in this series which terminated fatally, we had to deal with a streptococcus infection, as was demonstrated by the growth on culture media. In the first case there was a previous history of infection following a miscarriage which had occurred ten weeks before the patient was admitted to the hospital. At the time of the operation we were not able to demonstrate by coverslip examination any organisms in the pus that escaped. No drainage was employed. The infectious material may possibly have been introduced at the time of the operation, although it is quite likely that the process dated from the time of the miscarriage. In the second case the coverslip examination of the pus revealed no organisms, but on tubes inoculated from the pus streptococci were found. The abdomen was reopened on the second day after the operation under cocain anesthesia and washed out, drainage being afterwards instituted. The patient died on the third day. Cultures made from the lung at autopsy showed *Diplococcus pneumoniæ* and *B. coli communis;* in the liver, *B. mucosus capsulatus* was found, and in the peritoneum *Diplococcus pneumoniæ.* In this case, then, streptococci, though not demonstrable by coverslip examinations at the time of the operation, appeared in the culture tubes two days later. At the time of the autopsy only *Diplococcus pneumoniæ* was found in the peritoneal cavity.

CONCLUSIONS.

A careful analysis of this series, therefore, seems to justify the following conclusions:

1. The mortality following operations for suppurative diseases of the tubes and ovaries can be kept under 5 per cent.

2. The death rate is largely influenced by *a,* the virulence of the specific organisms present; *b,* the individual resistance of the patient; *c,* the time and manner of carrying out the operative technic.

3. The micro-organism most to be feared is *Streptococcus pyogenes,* but it must be borne in mind that this organism varies considerably in virulence.

4. Abdominal drainage following operations for pus in the tubes and ovaries is seldom called for, as the organisms are generally dead. Drainage becomes necessary only when it has been found impossible to remove the suppurative structures, or where perforation of the bowel

from the separation of dense adhesions is to be feared. Under these circumstances the best route is by the vagina.

5. The employment of sterile salt solution for irrigating the pelvic cavity will satisfactorily remove the pus or its products and the filling of the abdomen with salt solution will dilute and promote the rapid absorption of any inflammatory products that may be left behind.

6. The elevated position for 24 hours following the operation, with the abdomen filled with salt solution, tends to prevent the intestines and omentum from coming in contact with the immediate field of operation, and as a result adhesions are not so likely to form between the viscera and the incised surfaces.

7. Should symptoms of infection follow the closing of the wound in pus cases, we have, as a rule, sufficient time to reopen the abdomen and wash out the infective material that may have been left behind, or that may have been introduced at the time of the operation.

8. Operations for pus in the tubes and ovaries from the standpoint of the pus *per se* are not surrounded by more danger, as a rule, than those in which a purulent focus is not present.

Special Article.

VACATION NOTES.

G. FRANK LYDSTON, M.D.
Professor of Genito-Urinary Surgery, Medical Department State University of Illinois; Surgeon to St. Mary's Hospital.
CHICAGO.

1. HONOLULU.

There is but one way for a lazy doctor to enjoy himself, and that is to get aboard a sea-going vessel and keep going till his money gives out. He must select a far away destination, and get a through ticket so as to avoid the temptation to become industrious again, and insure against the necessity of swimming home. I selected Australia, via Hawaii, Samoa and New Zealand, and can confidently recommend the trip as the pleasantest and most healthful imaginable. The Pacific weather during September is ideal. Contrary to my expectations it was at no time too hot for comfort. Until Honolulu had been left far behind the weather was very cool. Even in equatorial regions the balmy trade winds redeemed the situation. I was informed that the trip was usually quite as pleasant as I found it. This is an important point for invalids, to whom the enervating effects of very hot weather are likely to be detrimental. My experience with Panama had led me to expect a similarly torrid heat at the corresponding latitude, and the cool breezes of the South Seas came as a most agreeable surprise. Indeed, just before reaching Auckland, and on the sea between New Zealand and Australia, the temperature was lower than I liked, and, now I recall it, it was here that the only unpleasant part of the voyage was encountered—of which more anon.

One of the advantages of taking a late vacation is the scarcity of physicians one meets. When you do meet them the temptation to talk shop is too strong to be resisted, and—away goes the rest you seek. There was only one aboard the steamer. He talked shop, but as he was a Britisher and couldn't talk English, and I carefully concealed my profession, no harm was done. He discoursed learnedly of King Edward's case, and I at first thought he might be Treves, traveling incog. He displayed so much unclassified misinformation on appendicitis, however, that I soon disabused myself of this fallacious notion.

The Hawaiian Islands are destined to become very popular for invalids, and unless Honolulu becomes overgrown—which is not likely in the near future—this city will always be a favorite resort for them. The equable temperature and facilities for out-of-door living and sea bathing the year round constitute most favorable conditions for the chronically sick. Honolulu is a beautiful city and most advantageously situated, but a description of its various attractions would be out of place here. I could not help being impressed with the fact that the fate of the Sandwich Islands exemplifies the rapacity of the Caucasian. The thought that this beautiful country was once the undisputed property and ancestral home of the poor Kanakas one sees about the streets is somewhat depressing. On the main street stands the regal palace of King Kalakaua, now occupied as an official building by the United States Government. On the opposite side of the street, facing the palace, is a heroic statue of King Kamahameha the Great, founder of the dynasty which the revolution, incited and conducted by alien whites, overthrew. To me the statue was most pathetic.

Not the least of the attractions is the magnificent high school building given to the cause of education by Princess Ruth. It was formerly her palace. Ruth was celebrated especially for her great size. She weighed something like six hundred pounds. One of the instructors at the high school says that he uses her bathtub as a swimming pool.

Walking down the principal residence street I chanced to see on the gateposts of a quaintly-artistic Japanese dwelling the names of Dr. Ninomiya and Dr. Oyama. Reposing peacefully on the mat in front of the office entrance were six pairs of sandals, which had been removed by the doctors' patients before appearing in their most august presence. The idea occurred to me as I saw the evidences of material prosperity which those sandals presented, that a similar custom might be popular in Chicago. We can imagine a situation like this: Dr. G. Randstand opens his front door one fine morning and glances at his rival's doorstep across the way. What he sees there almost causes him heart paralysis. Calling his major domo he cries:

"Fujiyama! How now? What is here? That fool, Dr. A. Gallery Play, has fifteen pairs of sandals at his door. What means this, villain?"

Whereat replies Fujiyama, with profound salaam:

"Most Concentrated and Multitudinous Knowledge of All the Centuries, it means simply this: his man, McGinnis, rose too early for me this morning. But bear with me, my liege, and I will make amends."

And next morning G. Randstand finds seventeen pairs of sandals on his own threshold. His honor is avenged, for there are French heels and golf shoes among the job lot purchased at the Fair by the faithful Fujiyama.

Honolulu just at present is enjoying a period of sanitary comfort. Recently harassed by the plague, the disease has practically disappeared, and the health of the city is excellent. Contrary to the usual belief, a few lepers are said to be at large among the natives. It is claimed that these cases are not severe, and so long as the victims do not make themselves conspicuous they are not disturbed. No cases, of course, are to be found in the hospitals.

The principal hospital of Honolulu is the Queen's. This has 120 beds and an average census of 70. Both Kanakas and whites are received here. The Kanakas should have the preference, for the hospital was founded by Kamehameha IV in honor of Queen Emma Kaledokalani. On the wall of the reception room hangs a certificate of Queen Emma's life membership in the "Queen's Hospital Corporation," founded by the first president, Kamahameha IV, June 15, 1859. Here also hang excellent life-size portraits in oil of Queen Emma and King Liholiho, who reigned some forty years ago. One can not fail to be impressed by the face of good Queen Emma, which is beautiful and kindly, even from the Caucasian viewpoint.

The hospital is a rather old-fashioned, two-story structure, somewhat the worse for time and wear. It needs a modern aseptic operating room more than anything else. Considerable surgery is done here, the emergency service being especially good. I inquired particularly in regard to appendicitis, and found not only that a fair number of cases are treated here, but that radicalism is distinctly in favor. The nurses are mainly from San Francisco training schools. I asked one of

them if they had a training school at The Queen's. She replied: "Thank God, no." The nurses are mainly American. There is no obstetric service at Queen's. Such cases are sent to the Maternity Home.

The hospital is under the direct control of a lay superintendent, Mr. Eckhart, to whom I am indebted for much information regarding the hospital. The staff is composed of one resident physician, two visiting surgeons and two visiting physicians. There is the usual ornamental, i. e., "consulting" staff, twenty in number. Dr. G. B. Wood, one of Honolulu's successful physicians, is surgeon-in-chief. No contagious diseases are admitted to Queen's.

The spirits of the staff are buoyed up by the promise of a new and well-equipped modern hospital in the near future. With such a building the institution will be ideal. The grounds are a dream of Fairy Land. Giant royal palms, cocoanut trees, pampas grass, the Pride of India—huge trees ablaze with scarlet bloom—passion trees, date palms, and every conceivable variety of tropic plant and flower serve to make the spacious grounds a paradise for the convalescent sick. A drive or walk through the main isle of stately palms can not soon be forgotten.

There is a small Japanese hospital in Honolulu, but it is unworthy of more than bare mention. The Army and Navy Hospital really deserves but little more attention. Patriotism, and the desire to give Uncle Sam a "hunch" impel me, however, to say something about it.

The hospital was established in 1898. It is now occupying "temporary quarters," which are about as good as Uncle Sam's sick are likely to get for some time to come. The institution consists of several low, one-story buildings built bungalow fashion. There are no separate rooms, only wards. The capacity of the wards is thirty-five. There were only nine patients at the time of my visit. All classes of cases are taken, but were it not for the venereal cases, the hospital, like Othello, would soon find its occupation gone. An occasional surgical case drifts in, however. Three or four cases of appendicitis have been treated there. Radicalism is the watchward, and the cases have all terminated favorably. Even Uncle Sam has awakened, and it is high time for "conservatism" to drop its fetiches. The surgeon in charge is Col. J. B. Girard. I had expected to find our old friend, A. C. Girard, formerly of Fort Sheridan, not noticing the difference in initials, but was doubly disappointed in finding, not only that the surgeon was absent, but that he was not the Girard whom I knew.

(To be continued.)

Clinical Report.

A CASE OF SCOTOMA AURIS PARTIALE CENTRALE ET PERIPHERICUM.*

EMIL AMBERG, M.D.
DETROIT.

Miss J. Sch., aged about 40, has been for some time under treatment for otitis media catarrhalis chronica, which may have set in, as patient thinks, after an attack of grippe two years ago, on which occasion she took quinin. There did not seem to be anything unusual in her case.

When patient consulted me again, Nov. 12, 1902, she told me that she was surprised to find out, accidentally, that she could hear a clock at home when the clock was in a position upward from her right ear, but that she could not hear the same clock, at the same distance, when the clock was on a level with the ear. I examined the patient with a watch, which can be heard normally at a distance of about 100-150 inches, and could confirm the patient's own observation. At a distance of about 3¾ inches the watch was heard at a height corresponding about to the top of the auricle, whereas the watch was not heard at the same distance directly opposite the canal and below. On the left side I found that the watch was heard, at very reduced hearing distance, opposite the canal and not above and below the auricle.

November 18 I examined the patient again, repeatedly, and found she almost constantly heard the watch (+) or did not hear it (—) when the watch was in places indicated in the diagram.

(Diagram.) 1. + 2. +a 3. + 4. + 5. +

+(|− ±(+b− −+)+ ±(−− ±+)+

− − − − −

1 to 3, before treatment with Eustachian catheter, Nov. 18, 1902:
1. Right ear. Watch in a frontal distance of about three inches.
2. Right ear. Watch in a frontal distance of about two inches. (*a*) Very loud; (*b*) not so loud.
3. Left ear. Watch in a frontal distance of about two inches.
4 and 5. After treatment with the Eustachian catheter.
4. Right ear. Watch in a frontal distance of about 3½ inches.
5. Left ear. Watch in a frontal distance of about 2¼ inches.

The findings in the case reported are extraordinary. All I can find in the latest edition of Politzer's text-book are a few lines on page 629: "Brunschwig gave the name of scotoma auris, an anomaly of perception, to a phenomenon consisting in the fact that in single cases a source of sound, e. g., a watch, is heard at a certain distance; that it is not, however, heard at a certain point when brought nearer to the ear. Guye (Records of Conference at Brussels, 1888) finds the explanation in the prevention of perception of the sound by the normal ear by the 'shadows of sound' which are created when the source of sound is brought nearer to the affected ear."

Gradenigo, on page 552, of the second volume of Schwartze's Handbuch der Ohrenheilkunde, says: "I will mention here another phenomenon which has been observed for the first time by Brunschwig in Baratoux's clinic, and which has been described later in five cases by Longhi. This consists in the fact that there exists a negative field of perception for a certain sound (watch, tuning fork, etc.) in the hearing distance of an ear: E. g., the sound of the tuning fork was heard in a distance of 25-15 cm. from the ear, from here until to a distance of 10 cm. perception suddenly ceased, and appeared again immediately near the concha (in a case of Longhi). In these cases there existed a very marked diminution of hearing in the other ear, but it did not seem to have any influence on the phenomenon. (Shadows of sound of Guye.) There existed catarrhal lesions of the middle ear, and portions of the drum membrane were atrophic and cicatricial. Longhi was, therefore, inclined to explain the symptoms by considering the difference in tension of the various segments, by which there would be created an interference of the sound waves. He also thinks that the muscles of the tympanic cavity are probably of influence. In these cases there was no phenomenon present which could be referred to the inner ear."

If we consider these remarks we see that no report is given about the phenomenon observed in my case. Furthermore, it appears to me that the name scotoma auris does not cover the symptoms. At least, we do not learn, from these reports, that the examination has been extended to this lateral periphery of the field of hearing. It would, therefore, seem appropriate, in my opinion, to propose, for the phenomenon reported by Longhi, the name: "Scotoma Auris Centrale Partiale," whereas I should like to name the phenomenon observed in my patient: "Scotoma Auris Partiale Centrale et Periphericum." The probable cause may perhaps be looked for:

1. In the formation of the auricle and the concha.
2. In the formation of the meatus.
3. In the changes in the membrana tympana corresponding to similar changes which we find in the eye and which we name astigmatism.
4. In changes in the tympanic cavity.
5. In affections which we call functional neuroses.

I do not attempt to explain the phenomenon in our patient, but I am inclined to attribute it to the formation of the concha and meatus, and the quality of the membrana tympani.

November 27 the symptom was less constant, and on December 2 it could not be demonstrated. The patient reports, however, that the clock at home is still heard better in the right ear when held higher. It is not impossible that the symptom may be attributed to a disturbance classifiable under the fifth cause enumerated above.

CATARACT IN INDIA.

The enormous number of operations done for cataract by the ophthalmic surgeons of India is amazing. In a recent article R. H. Elliot,[1] of the Government Ophthalmic Hospital, Madras, reports a series of 500 consecutive operations for primary cataract performed in five months. A little over a year ago several of the great cataract operators of India published articles[2] on this subject. At that time T. H. Pope based his conclusions on the subject of cataract extraction on 5,290 operations between 1896 and 1901, and over 4,000 done before 1896. Mr. Henry Smith, of the Jullender Civil Hospital, reported 1,804 extractions of cataract from June 1, 1899, to May 1, 1900, and 1,650 extractions from May 1, 1900, to April 2, 1901. Mr. J. Lewtas wrote of 147 extractions during the "past three months." Mr. Park of Jaipur reported 2,414 operations in five years. Mr. Collins, the assistant surgeon of the Madras Government Hospital, who helped Mr. Elliot in his operations, has seen about 12,000 extractions.

To make these numbers more appreciable, it is interesting to compare the number of cataract operations done in the largest eye hospital in America. At this hospital,[3] with its 25,000 to 30,000 new eye patients per year, 180 extractions were done in 1899, 182 in 1900 and 162 in 1901. And it is striking to compare the numbers reported by the Anglo-Indian surgeons with those of the greatest cataract operator in America. This surgeon, who began as long ago as 1868, when he reported 200 extractions, speaks, in a private letter, of having done over 4,000 cataract operations, and of his despairing of living long enough to do another 1,000.

When Mr. Smith's report appeared we were, of course, astonished at his statement that he had done 44 extractions on each of two days, and the conclusion seemed fair that a record of 44 operations for cataract in one day would for years remain unbeaten. Mr. Elliot has broken this record. On one day he did 53 extractions. This certainly is the record for cataract operations in one day, and will probably stand for a while. On three other occasions Mr. Elliot did more than 40 extractions in one morning.

Noting this immense number of operations, the idea occurs to one's mind that maybe the very numbers would make these operators careless. The reading of these articles banishes this idea. For instance, Pope, in his general remarks, gives it as his opinion—after 9,000 operations—that the surgeon should refrain from being in a hurry to publish his views in regard to what he thinks is the best method of operation and as to what are the causes of different complications. The article from Elliot, which, by the way, we imagine may be considered as a report of the latest methods and views from the Government Ophthalmic Hospital, Madras, is full of interest. Of course, anything on cataract coming from the Madras hospital must command attention; a few of the procedures practiced by Elliot are particularly worthy of note. That of lacerating the capsule of the lens, as he does it, by means of a Bowman stop-needle, before the section is made, appears to have advantages over the method as practiced in this country and Europe, of doing the capsulotomy after the section is made. He also calls attention to the value of morphia given hypodermically when the patient is nervous and will not obey. As a routine procedure, iridectomy is performed, and at the time of the extraction; in the 500 cases iridectomy was done in 484 of them. He washes out the cortical debris by irrigation, using MacKeown's irrigator, and says he owes a great debt to Professor MacKeown for allowing him to witness his method of using his apparatus. This irrigator, according to Elliot, by removing debris expedites recovery and minimizes the need for subsequent capsulotomy, dispenses with the introduction of instruments into the eye after the escape of the nucleus, and has enabled him to operate fearlessly on a large number of very immature cataracts, in which, without it, he would not have ventured to interfere.

It would seem that an operation like that of extraction of cataract (we might modify this statement by speaking of the operation in the hands of the average operator) could have been perfected by this time. This has not been done, and argument over different methods and procedures continues in the highest quarters. In the final adjustment of this operation, we venture the opinion that the methods of the Anglo-Indian ophthalmic surgeons will have an important place.

THE PROFESSIONAL SPIRIT.

Very few of us probably ever really give any very serious thought to what constitutes the difference between the professions as such and the other means of getting a livelihood. That there is a certain social distinction made we are all aware, but it might puzzle some of us to give an adequate accounting for its existence. This distinction is not in externals, though they have their effect. Perhaps most of us would first assume that it is based on the educational culture that the professions are supposed to require of their members. This has also, beyond question, its influence in creating the popular distinction, but it alone does not account for it altogether. We have had learned black-

smiths, stonemasons and shoemakers, but no one included them among professional men so long as they followed their occupation. Mere learning does not inspire popular respect to more than a very limited extent; there must be something more. Not all professional men are respected or respectable, but there is certainly a sort of prestige that exists of the professions as such.

Perhaps the best explanation, at least as regards the profession of medicine, is that given in a recent address by Professor Smart[1] of the University of Glasgow, which seems to us to contain some ideas that are well worthy of our consideration. He asks what differentiates the professions from the trades, and answers his question by quoting Ruskin, who "with all his extravagances saw right through to the heart of things." Ruskin asked why the common consent of mankind gives the precedence to the soldier over the merchant, and gave as the reason that the former held his life at the service of the state. We know that "put him in a fortress breach, with all the pleasures of the world behind him and only death and duty in front of him, he will keep his face to the front." It is the same with the true professional man, and more than all with the physician, who, like the soldier, but much more constantly, risks life and health for others' sake. It is not in this, however, that we are to find the true secret of the professional spirit and the reason of the honor in which it is held. There are plenty of men who risk life daily for a wage, and who think of nothing higher. The mere risk of the occupation is a secondary matter, the real distinction is, as Smart says, the putting of the work before the wage. There are, as he says, many physicians who will disclaim this, who will say that they do their work for the pay, but it is a poor-spirited physician and also an exceptional one whose practice coincides with this, whatever may be his professed theory. The professional spirit influences conduct even of those who would disavow it; professional pride and self-respect make the interests of the patients superior to one's individual interests and convenience. The Code of Ethics is only a formulated statement of the principles that unconsciously influence every medical practitioner worthy of the name. The public, therefore, puts confidence in the physician and regards him in a very different light from the tradesman and mere wage earner, whose business morals have personal interest as the chief good. Of course, there are many exceptions, tradesmen and mechanics and others who put their conscience into their work and these, too, have the true professional spirit, but they do not to the public represent their class or earn for it the regard that is given to the professional man.

It does not follow that we should neglect our interests, the laborer in these fields as in others is worthy of his hire, but we must keep ourselves clear of the taint of commercialism, the spirit that makes the tradesman's motto, at least too often, *"caveat emptor"*—let the buyer look out for himself. With us the word should be, as Smart suggests, *"caveat venditor"*—let us see first that we do good service for our wage. In times like these, with the present tendencies of labor agitations on the one hand and of combinations and trusts on the other, it is especially needful that we should keep up and live up to our best traditions and continue to earn the honorable estimation that has heretofore been given us.

1. Lancet, December 6. "Address on the Meaning of a Profession," delivered at the opening of the winter session at Anderson's College Medical School, Oct. 17, 1902.

THE CLINICAL SIGNIFICANCE OF LEUCOCYTOSIS.

Study of the blood has within the past two decades come to be an important aid in clinical diagnosis. Microscopic examination and culture methods often disclose the presence of parasites in the blood, and the specific agglutinating influence of the serum on colonies of certain bacteria constitutes a most valuable diagnostic guide, while a determination of the specific gravity, of the hemoglobin percentage and of the number of red and white corpuscles respectively, frequently furnishes useful information. An increase in the number of colorless corpuscles had long been known to occur physiologically during the digestive process, and pathologically in conjunction with leukemia. Under the condition first named the leucocytosis is transitory, while under the latter it is persistent. Increasing experience, however, showed that an increase in the number of leucocytes occurs in association with various inflammatory disorders, such as pneumonia, suppurative processes, etc., while the number remains unchanged or even undergoes reduction under other conditions, as, for instance, in the presence of uncomplicated typhoid fever. A distinct advance was made when it was learned that the colorless corpuscles were not all alike, but really consisted of several varieties that could be readily differentiated by means of their size, the number and form of their nuclei and their reaction to special stains. Thus, it has been found that the small mononuclear lymphocytes are increased after the ingestion of food and in cases of lymphatic leukemia, while myelocytes are characteristic of splenomedullary leukemia, in connection with which they may be present in large numbers. The eosinophile cells undergo marked increase in cases of trichinosis and probably other forms of animal parasitism. As a rule, however, the increase in the number of white blood corpuscles constituting leucocytosis involves especially the polymorphonuclear cells, which appear to play an active part in the process of phagocytosis. According to the commonly accepted definition leucocytosis consists in an increase in the number of white blood corpuscles in the peripheral blood, generally with a marked absolute and relative gain in the polymorphonuclear cells, but in a recent communication, Dr. Robert N. Willson[1] questions the correctness of this

1. Proceedings of the Philadelphia County Medical Society, December, 1902, p. 396.

definition, maintaining that the proportion of polymorphonuclear leucocytes may be increased without increase in the total number of leucocytes, and vice versa. To the former condition he applies the designation relative leucocytosis, and from his experience he concludes that when this is present it is suggestive of the existence of suppuration or of some other active inflammatory process in conjunction with marked depression of the resisting forces of the body. As to the clinical significance of leucocytosis, Dr. Willson points out that it must be looked on as only one clinical sign that should receive consideration in relation to all of the other phenomena in the case.

ACUTE AND CHRONIC INFLUENZA.

The diagnosis of influenza, even in times of epidemic, is not always easy, and by no means certain, in the absence of bacteriologic evidence. Catarrhal symptoms referable to the respiratory and digestive tracts, articular and muscular pains, elevation of temperature and other manifestations supposed to be more or less distinctive of influenza are not rare, singly or collectively, as a result of a variety of causes, particularly during the cold season. It would, therefore, seem that the demonstration of influenza-bacilli in the discharges or the blood is, at the present time, as important a factor in the diagnosis of influenza as is the demonstration of tubercle bacilli or of diphtheria bacilli in the diagnosis of tuberculosis or diphtheria.

The following method for staining the sputum for various bacteria is described by Dr. Wm. H. Smith,[1] in whose hands it has proved most serviceable. The dried and fixed cover-glass preparation is first stained with anilin-oil gentian-violet, the excess of which is washed away with a solution consisting of 1 part of iodin, 2 of potassium iodid and 300 of water. The specimen is then covered with this solution and heated. It is next decolorized as much as possible with 95 per cent. alcohol, then washed for a few seconds in a mixture of 4 parts of 95 per cent. alcohol and 6 parts of ether, and next in water, and exposed for a few seconds to the action of a saturated solution of eosin in water. The excess of eosin is washed off with Löffler's alkaline methylene-blue, the specimen again heated, decolorized slightly with 95 per cent. alcohol, washed in absolute alcohol, cleared with xylol and mounted in Canada balsam. The protoplasm of the leucocytes, lymphocytes, erythrocytes and other cells is stained red by the eosin, the nuclei of the cells blue. Micro-organisms that do not take Gram's stain appear black or deep violet, while those that take this stain appear blue. Capsules and cilia when present are stained red by eosin.

Tubercle bacilli require special staining by one of the usual methods. The special stain described was employed by Dr. Frederick T. Lord,[2] in a study of the sputum in 100 cases for the purpose of determining the cause of the cough and expectoration present, and in which examination for tubercle bacilli had failed to disclose their presence. In 60 of these cases influenza bacilli were found in varying numbers, and in 29 of these the bacilli were present in overwhelming numbers. As a result of his observations Dr. Lord concludes that infection with influenza bacilli is prevalent apart from an epidemic of influenza, and that there is nothing distinctive in the clinical manifestations to which the disease gives rise apart from their epidemic occurrence, so that the diagnosis can be made with certainty only by examination of the sputum for influenza bacilli. The duration of the cough and expectoration after an attack of acute influenza does not usually exceed six weeks, but in some cases it may be extended over months and years. Many of the cases heretofore classified as chronic bronchitis are in reality examples of chronic influenza. Cases of this character with paroxysmal dyspnea may closely resemble asthma. Chronic influenza is not infrequently mistaken for pulmonary tuberculosis.

IMPROVED TREATMENT OF EMPYEMA.

The medical treatment of empyema has long been a disappointment and the operative treatment has not been all that could be desired. Though old as Hippocrates operative intervention has come to be considered more in the sphere of the surgeon than the physician, and anything, therefore, that will render it more practicable for the practitioner and a more early and general recourse is a boon to mankind.

In a paper on the subject of the treatment of suppurative pleurisy, read before the Illinois State Medical Society, Dr. E. Fletcher Ingals[1] recommends an operation which can be performed by the average practitioner and which seems in many respects to be an advance on the methods heretofore employed. It consists in the introduction of a double drainage tube through a trocar inserted in the intercostal space and secured there after withdrawal of the instrument in such a way that it is perfectly under the control of the operator. Ingals gives an analysis of the cases in which this method was employ with the percentage of recoveries of 100 in early cases and 64 in those of long duration. He thinks if this operation can be performed early, in cases of empyema caused by the pneumococcus, from 95 to 98 per cent. of recoveries can be expected, and in all other cases in which the side is not retracted it will give as good results as any other operation. It does not require general anesthesia and is no bar to subsequent exsection of the rib if that is thought advisable. He advises the latter operation if after a few months a cavity remains that can not collapse because of induration or rigidity of its walls. Exsection of the rib, of course, of itself is the elective method where the intercostal

1. Illinois Med. Jour., January.

spaces are greatly narrowed by chest retraction, but in other cases in which such has not occurred, the double drainage tube and exclusion of air for several days has much greater advantages. So far as we have seen, this particular operation has not been recommended by any other operator, but it is with the results attained a decided advance over other methods. The outcome of empyema, whether in the form of early fatality or prolonged chronic disturbance without any expectation of an ultimate cure, is such that an easy operation like the above described, performable in the early stages and hardly more serious than aspiration, should be welcomed. Ingals believes, however, that aspiration should precede any operation for empyema and should be repeated at intervals of several days until the cavity is emptied, and then, after allowing a short time for reaccumulation of matter, a radical operation should be done. In this way we may expect successful results.

APPENDICITIS IN FASHION IN ENGLAND.

Sometime ago The Journal prophesied a probable greater extension of the disease of appendicitis in British high life through the example set by the king. This prophecy is reported by the daily press as having been fulfilled. Appendicitis is increasing, it is said, in Great Britain by leaps and bounds so that operations for this disease are becoming more and more common. The Countess of Dudley, one of England's noted beauties, is one of the latest who has gone through the operation, and if we had recourse to all the records perhaps we would find, as is said by newspaper writers, that aristocratic appendices are being amputated at very short intervals. What will be the outcome and how long the epidemic will last is beyond knowledge, and we have stopped foretelling.

THE NEW INDEX MEDICUS.

A circular has been issued announcing the renewal of the publication of the *Index Medicus* by the Carnegie Institution, Washington, D. C., subscription price paid in advance $5.00 per annum in the United States and Canada, and in foreign countries 25 shillings or marks, or 35 francs or lire. The plan is to follow out much the same course as in the earlier publications, giving the titles in full of books, pamphlets, theses, contributions to co-operative work, and original articles in the journals, transactions of medical and scientific societies, all arranged under subject headings. The titles in certain languages, such as the Russian, Polish, Swedish, Danish, Turkish, Hungarian, Bohemian, Roumanian, Japanese and Chinese, are to be translated into English. Other languages which are presumably more generally known will be left untranslated. A good point in the new publication is the promise of the editor that while indexing all real original matter it will not include reports of progress or all copies of an article which may appear in other journals. It was somewhat of an embarrassment in utilizing the *Index Medicus* formerly published to find so many cases of repetition of the same title owing to the common habit of cumbering the record by certain authors, a notable instance[1] of which has recently been commented on in The Journal and elsewhere. The profession is to be congratulated on the fact that the Carnegie Institution has thus undertaken the republication of the *Index Medicus*.

1. See The Journal A. M. A., Nov. 22, 1902, p. 1326.

CORRESPONDENCE SCHOOLS FOR NURSES.

Short cuts into medicine and its allied professions are becoming numerous. Before us is an advertisement of the Chicago Correspondence School of Nursing of Pierre, S. D., licensed to transact business in Illinois with a state capital of $2,500. If there is any occupation that would seem to us to require direct special object-teaching and experience, it is nursing, and what class of products the correspondence school will turn out is a matter of some interest. Nursing is a practical handicraft, as little theoretical in many respects as anything can be, and any part of it that can be taught by didactic teaching or correspondence is comparatively minute and unimportant. The value of well-trained nurses is appreciated, not only by physician and patient, but by the general public, and it is very natural that attempts should be made to furnish a cheap imitation; but we as physicians, knowing what poor nurses may be, are interested in forestalling such attempts as far as possible. If there is to be a correspondence school of nurses let us make sure that we do not get any of their graduates among our aids. She would be a very exceptional one who would be of much use.

COSMIC MICROBES.

Those who have read Mr. H. G. Wells' ingenious fiction, "The War of the Worlds," in which the superior beings from another planet threatened to destroy the existing population of the earth, but were overcome by the microbes which they found, will be interested in the recent speculation of the reverse of this by a Western scientist. He asks, is there any reason why small living bodies, such as spores or microbes, should not be floating about by themselves in the interstellar space and, in some ways which are easily conceivable, from time to time enter into our atmosphere and infect our planet? In this way the origin of new diseases and possibly of many other phenomena which we can not foretell might be accounted for. The idea is not an altogether new or extravagant one; Sir William Thomson (Lord Kelvin) theorized on the introduction of life into our planet by meteoric bodies. He suggested that spores floating about in the atmosphere of this or some similar planet might easily become detached in the upper regions where we know perpetual hurricanes exist and, if shot off on a tangent, might wander through space beyond the reach of gravitation until sometime they come within our own or some other sphere of attraction and develop under the conditions that they find. Recent experiments have shown that the greatest degree of cold that can be artificially produced, probably fully as great as that in the interstellar space, does not have an effect on bacterial life, at least not on all forms of it. In this way the prospects of the possible morbidity on our earth, and perhaps of some things that are much better, is illimitable. The speculation is one that is at least respectable and perhaps might be seriously considered.

Medical News.

ILLINOIS.

Vital Statistics.—Peoria reports 745 deaths during 1902, a death rate of 10.64 per 1,000.——Danville's death rate for the year was 18.3 per 1,000, consumption, accidents and heart disease leading in the order named.

Typhoid Rife in Elgin.—More than fifty school children of Elgin are ill with typhoid fever, and the president of the board of education has issued a proclamation urging boiling of water and individual drinking cups. The water supply of Elgin is taken from Fox river, which is said to be not above reproach.

Proposed Legislation.—A bill to be introduced abolishes the office of coroner and transfers his duties to some other officer—another provides for a board of medical examiners, separate from the State Board of Health—a third looks to state isolation and care of consumptives—a fourth recommends the establishment of a state home for epileptics.

Personal.—Drs. Charles W. Compton, S. R. Hopkins, John W. Kelly, Herman H. Tuttle and Edmund A. Walsh have been added to the attending staff of St. John's Hospital, Springfield.——Dr. Thomas W. Keyes, Leroy, after a rest of two years, has resumed practice.——Dr. Myron L. Huntington, Moline, dreaming he was attacked by burglars, seized a revolver and shot himself in the right leg.

Chicago.

Fire Damage.—An explosion of gas followed by fire, January 2, destroyed the library and office equipment of Dr. Orrin B. Hayden.

Smallpox.—During last week 6 smallpox patients, none of whom had ever been properly vaccinated, were sent to the isolation hospital. Three of the patients were waiters in restaurants, one of whom claimed to have contracted the disease in Toronto, and another in Cincinnati.

Personal.—Dr. and Mrs. Daniel R. Brower left Chicago, January 12, on a silver-wedding trip to the West Indies. They will return in about four weeks.——Dr. David O'Shea has returned from Europe.——Dr. Franklin C. Wells has gone to New York City, where he will be chief of the medical inspection department of the Equitable Life Assurance Society.

The Week's Deaths.—During the week ended January 10 625 deaths were reported, equivalent to an annual mortality rate of 17.29 per 1,000, which compares unfavorably with the rate for the corresponding week of 1902, which was 14.79 per 1,000. There was a marked increase in the deaths over 60 years of age and in bronchitis, consumption, pneumonia, typhoid fever, and especially in scarlet fever, as compared with the previous week.

Street-car Colds.—Under this heading the department of health offers the following seasonable advice:

"Street-car colds" are, in the experience of every physician in general practice, increasing with frightful rapidity. Pneumonia and bronchitis, as direct results, are endemic in every part of the city. Since the first of the year there has been a 22 per cent. increase in the deaths from these two diseases, and, as compared with the first ten days of 1902, the increase is a little more than 41 per cent.

Again the department urges that every able-bodied person shun the street cars, both surface and elevated, as far as possible.

The Coal Situation and Public Health.—The department of health thus summarizes the effects of the present fuel situation on the public health:

Fully 10 per cent., or nearly 200,000 residents of Chicago, are to-day suffering from ailments of a grave character caused by privation and exposure resulting from the coal famine. Already these ailments are reflected in the enormous increase of deaths among those at the extremes of life—the young and the aged, in both of whom the powers of vital resistance are at the lowest. Since the first of the year there has been an increase of nearly 20 (19.2) per cent. in the number of deaths among those under 5 years of age over the number in the corresponding period of last year, when this death rate was about normal. Among those over 60 years of age the increase is much greater—24 per cent. last week over the week previous and 36.7 per cent. over the normal rate of the corresponding period of 1902.

This excess of increased death-rate among the aged is caused chiefly by the effects of cold and exposure in hastening to a fatal termination many of the chronic diseases, the sufferers from which under ordinary conditions might have survived for many years.

MARYLAND.

Smallpox in Allegany County.—James M. Spear, health officer of Cumberland, has discovered that a case of smallpox has been concealed there since Dec. 7, 1902. Two new cases in the same house led to the discovery. Dr. Spear will take the case before the grand jury.

Tuberculosis Data.—The tuberculosis commission of the state of Maryland, Dr. William S. Thayer, president, met, January 10, at the office of the State Board of Health. Dr. Marshall Price was appointed medical officer of the commission. He will have charge of all statistics and the general work of the commission. Inquiries will be sent at once to institutions and physicians, with blanks for regular reports. Dr. William H. Welch has endorsed the work of the commission with the following letter addressed to the medical profession of the state:

The Tuberculosis Commission of Maryland has permission, under certain necessary restrictions, to use the laboratory and death records of the State Board of Health for the purpose of its investigation. The State Board of Health also commends in the strongest possible manner the work of this commission to the interest and aid of practicing physicians. If every physician in the state will, to the best of his ability, answer the few inquiries which the tuberculosis commission will make in the next year, we shall obtain what all of us feel is a pressing need—an accurate view of the amount and distribution of tuberculosis in Maryland.

Baltimore.

A memorial meeting in honor of the late Dr. Martin B. Billingslea was held January 12, at which addresses were made by the representatives of the various organizations to which he had belonged.

Measles and Mortality.—The epidemic of measles reached the high-water mark last week, 300 cases being reported. There were 5 deaths directly attributed to measles and about 50 from respiratory diseases, many no doubt caused by measles. The total mortality, 217 for the week, was unusually large, 20.39 per 1,000.

Presbyterian Eye, Ear and Throat Hospital.—The twenty-fifth anniversary of the founding of this special hospital, one of the largest of its kind in America, took place January 9. The report shows that 11,317 patients were treated during the year, representing 40,204 visits. The patients were divided as follows: Eye department, 7,137; ear department, 2,007; throat department, 2,103. The question of endowment was discussed, and the secretary announced that offers amounting to $15,000 had been made conditional on the collection of an equal sum. Dr. Francis M. Chisolm was re-elected secretary, and Drs. Hiram Woods and John A. Winslow members of the board. The institution owes its origin to the energy of Dr. Julian J. Chisolm, at present emeritus professor of eye and ear diseases in the University of Maryland, who has retired from practice and resides at Petersburg, Va.

Purity of Ice Cream.—Miss Henrietta M. Thomas, a student at the Woman's Medical College, has been conducting an investigation in the City Bacteriological Laboratory under Dr. W. Royal Stokes, with reference to the purity of ice cream. The primary object was to discover the typhoid bacillus, but none of these were found. Other germs, however, were discovered, as *B. coli*, *Bacillus annulatus*, gas bacillus, *Bacillus arborescens*, pneumococcus, streptococcus, yellow, lemon and cream-colored tetrads and yeast. About 25 specimens of "hokey-pokey" and high-priced ice cream from all parts of the city were examined. The colon bacillus was omnipresent. In one specimen injected into the abdominal cavity of a guinea-pig, death ensued from general peritonitis in 24 hours; the only organism recovered was *B. coli* from the blood of the liver. Several specimens of snowballs all contained *B. coli*, indicating contamination. The specimens were extremely poor in fat, especially the cheaper sorts, the percentage being never higher than 11.2, and in one case as low as 1.25. The number of bacteria in 1 c.c. varied from 378,000 to 36,600,000, being practically the same as in fresh cream. This remarkable result is probably due to the fact that there are certain kinds of bacteria which are reduced by freezing (Prudden). The conclusion is either that the cows from which the milk was obtained were infected or that the handling of the ice cream was very careless, thus rendering it unsuitable for food. Both of these causes of contamination can, and ought to be obviated.

NEW YORK.

Needs Hospital.—The Auburn Board of Health has asked the common council for an appropriation of $25,000 for a new isolation hospital for smallpox patients.

Personal.—Dr. Montgomery E. Leary, Rochester, has resigned as coroner's physician of Monroe County, and Dr. Irving E. Harris has been appointed in his stead.——Dr. Francis P. O'Neil of Elmira, N. Y., has been appointed on the resident

staff of the City Hospital, Baltimore, attached to the College of Physicians and Surgeons.

The Coroner's Office.—The annual report of the board of coroners shows there were last year 2,820 deaths which called for investigation; that as a result of such investigation 543 persons were held to the grand jury; that 1,236 inquests were held and 644 autopsies performed. The board asks for a chemical and bacteriologic laboratory and for a larger clerical force. The committee of the county medical society appointed to consider the advisability of abolishing the coroner's office reported in favor of so doing, but the coroners and their friends made such a vigorous protest that, after a special evening devoted to a discussion of the subject, the society finally voted to reject the report of its committee. On the other hand, it is announced that the counsel for the New York county and state medical associations has submitted to the district attorney the draft of a bill, to be introduced in the legislature, which calls for the abolition of the coroner's office, and the substitution of experienced pathologists. The district attorney is reported to approve of the bill.

State Hospitals for the Insane.—The governor, in his message, devotes considerable space to the state hospitals for the insane, and particularly to the workings of the new system which he inaugurated a year ago. He asserts that the new law has resulted in the separation of the medical from the business administration of these institutions; has saved the state about $20,000 per annum; has limited the cost of new buildings to $450 per capita, and, above all, has absolutely fixed the responsibility for the administration of these institutions in the State Commission in Lunacy. The recoveries during the past year have been only 1,125, as against 1,200 for 1901, but this is thought to be largely accounted for by the fact that certain local hospitals are now caring for the early and acute cases, so that a larger proportion of the cases coming to the state hospitals belong to the incurable class. Moreover, though the percentage of cures is less than in 1901 it is equal to the average for the preceding six years, and the death rate has been lower. He recommends the establishment of tuberculosis hospitals at six of the institutions at a cost of $90,000, thus reducing the danger of communicating this disease to other inmates. The commission in lunacy suggests that a new hospital for the care of recent cases of insanity be established in New York City.

New York City.

Beth Israel Hospital Aided.—The recent fair in Madison Square Garden realized about $25,000 for Beth Israel Hospital.

Addition to Harlem Hospital.—An extension for this overcrowded hospital has at last been secured in the shape of a three-story house. In it will be housed the dispensary, which at present is in a ramshackle structure built out over the river. It will also provide 30 beds for children and 20 beds for maternity cases.

Personal.—Dr. Albert H. Brundage, Brooklyn, has been elected president of the New York State Board of Pharmacy. ——Dr. Emily Duhning, on January 1, commenced a two years' term of service as interne and ambulance surgeon at Gouverneur Hospital.——Dr. Henry P. DeForest, Brooklyn, has been appointed a police surgeon, vice Dr. Benjamin Wood, retired on pension.

Croton Water Not Responsible.—The examinations of the Croton water made by the health department do not indicate that the water supply is responsible for the prevalence of typhoid. The health authorities are disposed to lay the blame on the use of oysters, clams, and some vegetables and milk. During the week ended January 3, 68 cases of typhoid fever were reported, which is in excess of the number for the corresponding period of last year.

Old Bellevue Landmark Gone.—Many medical students, as well as the physicians who in past years have had occasion to frequent the vicinity of Bellevue Hospital, will be interested to learn that the "coffee house," or more properly the Manhattan East Side Mission, which has long been situated opposite Bellevue Hospital, is a thing of the past. This mission was maintained by the New York Bible and Fruit Mission, an association originated by Mrs. Collins. The newer members of the association have lacked the enthusiasm which spurred on the original workers, and, as a consequence, the necessary funds have not been forthcoming. The Supreme Court has granted the petition of the directors for permission to wind up the affairs of the association.

Buffalo.

Bequest to Hospital.—Through the bequest of W. C. Mills the Buffalo General Hospital received $10,000.

Personal.—Dr. Frederick Zingsheim was elected to fill a vacancy in the department of children's diseases and Dr. Pietro Tartaro a vacancy in the department of skin diseases at the German Hospital.

Resolutions.—At a special meeting of the medical staff of the dispensary of the German Hospital, resolutions were adopted deploring the death of Dr. Jacob Kraus and eulogizing the many good qualities of the deceased.

Election of Staff.—At the annual election of officers of the staff of the German Hospital the following were re-elected: President, Dr. Charles A. W. Auel; vice-president, Dr. Marcello Hartwig, and secretary, Dr. Charles Weil.

Health Commissioner's Annual Report.—In the annual report of Health Commissioner Greene the following recommendations are made: A fumigation plant so that the department of health may supplement its work of discovery of infection by prevention of its spread; a filtering plant, as while the city water supply can be considered fairly good, it is not wholly free from danger because of the fact that the lake and the rivers are polluted to some extent by the cities draining into the lake above Buffalo. The possibility of typhoid fever from lake water must necessarily be present during certain periods of every year; its cause is one beyond present control, and therefore it is pertinent to consider practical means of overcoming the conditions and results as stated. During 1901-1902 there were 438 cases of smallpox in Buffalo, whereas at present there are but 5, and in each of these cases the contagion came from without.

PENNSYLVANIA.

Sued for Damages.—Dr. Louis H. Fackler, East Berlin, has been sued for $30,000 damages by W. G. Leas, for alleged neglect in the last illness of his wife.

Only One-Sixth Rejected.—Of the 77 applicants who recently took the examination before the State Medical Board 64 received license to practice—a failure of 16.5 per cent.

Typhoid at Bellefonte.—Bellefonte has an epidemic of typhoid fever, which is causing considerable local alarm. About 40 cases have already developed, with two deaths, and a number of patients critically ill.

Bacteriologic Laboratory for New Castle.—Councils have reported in favor of the establishment of a municipal bacteriologic laboratory, as suggested by the Lawrence County Medical Society, to be maintained from the public funds. The equipment of the laboratory will cost about $1,000, and $50 a month will be paid to a physician to be on duty at specified hours.

Health Board Resigns.—All the members of the board of health of Chester, Pa., have tendered their resignations, to take effect when their successors are appointed. The board, consisting of five members, have been accused of inefficiency in connection with the smallpox situation. The members claim, however, that they have no authority to enforce vaccination, and that their plans are not carried out.

In Trouble and Out.—A clergyman of Altoona was recently arrested at the instance of the secretary of the local board of health, charged with failing properly to fill out returns of marriages.——A verdict of not guilty has been returned in the case of D. C. Hancher against Dr. William A. Shannon, Ellwood, who was charged with being a "public nuisance" for not having reported a case of smallpox to the secretary of the Ellwood Board of Health. The costs were placed on the county.

The Quarantine Report.—According to the recent report of Dr. Heller, port physician to the State Quarantine Board, last year was an unusually busy one at the quarantine station. The total number of persons examined and detained was 73,090. Deaths reported on inward-bound vessels, 14; births, 5. Medical cases numbering 780 were treated at the hospital, and 405 surgical cases were treated by the quarantine surgeons. It is announced that the state has purchased the site on which the Marcus Hook Quarantine Station is located.

Philadelphia.

University Hospital To Be Enlarged.—The University of Pennsylvania Hospital is to be enlarged and improved. About $300,000 is to be expended, which will nearly double the capacity of the institution.

Expectoration Prohibited.—An ordinance has been passed by the common council making expectoration on the sidewalks, in public places and conveyances, a nuisance, and providing a penalty of $5 for violation of the ordinance.

Hospital Ordinance Signed.—Mayor Ashbridge has signed the ordinance for the purchase of the Macalester farm, in the Thirty-third Ward, for a site for a new municipal hospital. The farm contains 58 acres and will cost $1,160,000.

A Low Death Rate.—Statistics of the bureau of health for 1902 show a death rate of 17.67 per 1,000. This is the lowest rate since 1879, when it was 17.17 per 1,000. The prevalence of smallpox throughout the city last year added materially to the death rate.

Vacancy on House Staff.—A vacancy exists on the staff of the assistant visiting physicians to the Methodist Episcopal Hospital. Candidates must have the degrees of both A.B. and M.D. The assistant visiting physician is chief of the medical clinic for three months of each year.

Lectures on Tropical Hygiene.—Arrangements have been made by the trustees of Jefferson Medical College for Captain Charles F. Keifer, assistant surgeon, U. S. A., to deliver to the senior class of the college a series of eight lectures on tropical hygiene, limited to a consideration of purely tropical diseases.

More Money for Hospitals.—By the will of the late James Wilson a bequest of $1,000 is made to the Presbyterian Hospital.——In the distribution of a balance from the estate of Thomas Elkinton the following institutions receive $5,000 each: Jefferson Hospital, Orthopedic Hospital, Polyclinic Hospital, and Hospital of the University of Pennsylvania.

Staff Reappointed.—At a meeting of the Board of Charities and Correction, held December 30, the entire medical and surgical staff of the Philadelphia Hospital were reappointed for 1903. The following new appointments were made: Bacteriologist, as associate to Dr. L. Napoleon Boston; Dr. Randle C. Rosenberger; neurologist-registrar, Dr. T. H. Weissenberg.

College of Physicians Election.—At the annual election of officers by the College of Physicians, held January 7, the following were chosen: President, Dr. Horatio C. Wood; vice-president, Dr. Arthur V. Meigs; censors, Drs. Richard A. Cleeman, S. Weir Mitchell, Horace Y. Evans, Louis Starr; secretary, Dr. Thomas R. Neilson, and treasurer, Dr. Richard H. Harte.

Children's Hospital Staff.—At a meeting of the board of directors of the Children's Hospital, recently held, Dr. C. Y. White was appointed pathologist to take the place of Dr. Alfred Hand, Jr., who lately resigned; Dr. D. J. Miller was appointed visiting physician, instead of Dr. Alfred Stengel, resigned; and Dr. J. Claxton Gittings was appointed physician to the dispensary.

Death and Disease.—Scarcity of coal and the low water supply are perhaps largely responsible for the unusual number of cases of pneumonia and typhoid fever. During the week ended January 3, there were 90 deaths from pneumonia, 144 new cases of typhoid fever, and 13 new cases of smallpox. Orders have been issued to the vaccine physicians to begin a house-to-house canvass for the purpose of vaccination.

Typhoid, Smallpox and Pneumonia.—Typhoid fever may be said to be epidemic. For the week ended January 10, 217 new cases were reported. During the eight weeks previous to this date, 906 new cases developed. The low condition of the water in some of the reservoirs is thought to be a large causative factor. Within the week mentioned, 33 new cases of smallpox developed, and 108 deaths from pneumonia occurred.

Bequests to Charities.—Fifty-nine charitable institutions of Philadelphia were left sums of money, amounting in all to $69,500, by the will of Henry C. Cochran. The charitable bequests do not become operative until after the death of the benefactor's mother. The Pennsylvania Hospital is to receive $10,000, $5,000 of which is to be applied toward improving the accommodations for the insane. The Presbyterian Hospital receives $5,000 to endow a bed, the trustees of the University of Pennsylvania $5,000 for the endowment fund of the hospital and the Medico-Chirurgical Hospital $1,000.

WISCONSIN.

Physicians and Midwives Profit.—The county clerk of Milwaukee County has begun the annual payment of fees to physicians and midwives for filing certificates of births and deaths during the year ended Nov. 1, 1902. Nearly 600 orders will be issued, calling for $5,292.50.

Irregulars and Irregularities.—Henry Spencer, who practiced medicine in Rozellville under the name of Dr. Charles A. Clark, and was charged with making false representations to the State Board of Medical Examiners, to secure a license to practice, pleaded guilty, January 5, and was sentenced to one year's imprisonment in the House of Correction.——Adolph W. Dude, Milwaukee, under arrest on suspicion of having performed an illegal operation, has acknowledged that he is not a regularly licensed practitioner in the state.

Personal.—Dr. Alfred Elliott, who recently returned from Germany, has been appointed assistant house physician at the Oakwood Sanitarium, Lake Geneva.——Dr. H. Browall, assistant at Raon's Hospital, Merrill, has resigned.——Dr. Solon Marks, Milwaukee, for over a quarter of a century a member of the State Board of Health and for the greater part of that period president of the board, has been succeeded by Dr. Cornelius A. Harper, Madison.

The Right to Quarantine Smallpox.—On January 7, a temporary injunction was granted by the Outagamie County Circuit Court restraining the board of health of Appleton from removing to the pesthouse Mrs. Elizabeth Leonhardt, alleged to have smallpox. The complaint in the case, made by the woman and her husband, alleges that the board of health is not legally organized under the statutes of the state, and has no authority to quarantine or to confine in a pesthouse. There are now more than 20 cases in the pesthouse, and if that is closed by permanent injunction, it is threatened that a shotgun quarantine may be instituted.

GENERAL.

Mazatlan Plague Severe.—There is no spread of the plague yet reported from Mexico. Mazatlan is, however, unable thus far to stop the ravages of the disease in the city itself. Wholesale disinfection by burning all infected houses has been begun.

Chicago Most Healthful City.—For the seventh successive year, Chicago's death rate is lower than that of any other city of first magnitude. The death rate per 1,000 inhabitants of New York City (Manhattan and Bronx) was 19.18; of Boston, 18.58; Greater New York, 18.28; Philadelphia, 17.85; Chicago, 14.49. Chicago's infant and child mortality is the lowest of any city of its size.

Danish Tuberculosis Commission.—The royal commission which has been investigating tuberculosis recommends rigid laws. Some of the points proposed are: Reporting of cases, compulsory confinement of recalcitrant patients in special institutions, prohibition of infected persons from acting as nurses, teachers or physicians, erection of municipal phthisis hospitals, the state bearing half the cost and the extremely poor being treated free of charge.

Medical Member of the Isthmian Canal Commission.—The following is the text of the resolutions which we stated last week were adopted at the meeting of the American Association for the Advancement of Science, in Washington:

WHEREAS, The construction of the Isthmian canal is through a region in which without energetic sanitary control there is sure to be enormous loss of human life from preventable diseases, particularly from pernicious malaria and yellow fever, as well as great waste of energy and of money from disabilities caused by such diseases, and

WHEREAS, The measures for the restraint of these diseases, which have already achieved even their partial extermination in Cuba under American administration, require expert knowledge based on practical familiarity with tropical diseases, experience in the application of these measures, and large authority in their administration,

Resolved, That the American Association for the Advancement of Science begs most respectfully and earnestly to call to the attention of the President of the United States the importance of appointing as a member of the Isthmian Canal Commission a medical man possessed of the qualifications indicated. The association is convinced that the mere employment of such a sanitary expert by the commission will not be likely to secure the desired results.

Resolved, That the permanent secretary of the association transmit a copy of these resolutions to the President of the United States.

CANADA.

British Columbia Plague Quarantine.—Dr. A. T. Watt, superintendent of the British Columbia quarantine, has given notice of the establishment of new regulations on account of the epidemic of bubonic plague at San Francisco. The various steamers plying between San Francisco and Canadian ports have been notified and are warned to use funnels on their mooring lines at San Francisco to prevent rats coming on board.

Appointments at Trinity.—The Anatomy Department of Trinity Medical College has to a great extent been rearranged. Dr. George A. Bingham is now professor of anatomy as well as lecturer on surgical anatomy; Dr. Charles B. Shuttleworth, who recently returned from England, where he secured the Fellowship of the Royal College of Surgeons by examination,

has been appointed associate professor; Dr. T. Bedford Richardson, first senior assistant; Dr. George Elliott, second senior demonstrator, and Dr. Charles P. Lusk, third senior assistant demonstrator.

New Brunswick News.—About 800 patients were treated at the General Public Hospital of St. John during 1902.—— Dr. Thomas Walker has resigned as vice-president and treasurer of the General Public Hospital Commission of St. John.—— During the year 1902 there were reported 219 cases of contagious disease to the St. John Board of Health. The number of deaths in 1902 was 27 less than in 1901.——Dr. W. L. Ellis, the newly-appointed physician at the port of St. John, on December 31, ordered the deportation of some sixty immigrants who came over on the Elder-Dempster Line. Most of them were afflicted with trachoma.

FOREIGN.

The London influenza epidemic is rapidly decreasing.

Many British Insane.—The lunacy returns for 1902 show 148,631 in the United Kingdom and 110,713 of these were in England. The official view is that the increase is more apparent than real; that the case is rather one of accumulation; that if there be an increase it is not out of proportion to the increase of population. Mr. W. J. Corbet, however, thinks there is an alarming actual increase, and in an article in the January *Westminster Review* recommends an international conference to discuss means to check insanity.

Sydney Plague Prophylaxis.—In view of the state of affairs at San Francisco with regard to bubonic plague, the Sydney Board of Health decided, December 2, to enforce the regulations, without exception, concerning ships that have touched at plague ports. San Francisco has been made an exception, but the board fears to continue this plan. Vessels, however, that have consular certificates as to supervision of loading and as to having been properly fended off from the wharf to prevent rats from boarding, may be admitted as free from suspicion. Sydney does not want another taste of the plague.

LONDON LETTER.

A Galloping Field Hospital.

In distributing the prizes to the successful members of the Manchester Royal Army Medical Volunteers, Sir F. Treves put forward a novel proposal. The conflict in South Africa, he said, had shown the impossibility of supporting any army medical corps on a war footing. Wealthy as the country was, it could not bear the expenditure. The comparatively slight alteration that the recent commission had introduced into the corps would cost $500,000. In time of war the Army Medical Service must turn to volunteer aid, which, to be of any use, must have been organized. In connection with the Ladysmith relief column, to which he was attached, he felt how infinitely more serviceable the surgeons with the volunteer aid column would have been had they had a volunteer medical training. One weak point in the Army Medical Service was shown in the late war. There was no unit or outfit capable of following a rapidly moving cavalry column. He hoped that some rich philanthropist would provide means for experimenting in that direction and organizing practically a galloping field hospital. The problem had to be solved and it would be an exceedingly expensive one unless assistance was given by the generosity and enterprise of some wealthy man.

Sleeping Sickness.

Dr. Low, research scholar of the London School of Tropical Medicine and leader of the Royal Societies' Commission sent out by the government to investigate sleeping sickness, has returned to England. He states that the epidemic of sleeping sickness now raging in Uganda is of serious importance to that protectorate, and to the adjacent one of British East Africa. Though only detected a few years ago, it has now extended over a large area and is computed to have killed 20,000 to 30,000 people. It is spreading to new areas, and its virulence is apparently on the increase. The scientific reports of the commission are the property of the Royal Society and will be published in due course, but in the meantime it may be stated that the commission believe they have isolated the microbe that causes the disease. A scheme for the isolation of fresh cases occurring in new districts has been adopted. So far no white person has been attacked. Necropsies have demonstrated that one of the features of the disease is inflammation of the brain and its membranes. The course may be acute or chronic; in the latter case the duration may be six or seven months.

PARIS LETTER.

Microbiology of Gonococcic Arthritis.

Professor Vaquez and Dr. Laubry have had occasion recently to study the condition of joints affected by gonococcic arthritis, and the results obtained show that the bacteriologic condition is not the same in all cases. In two patients suffering from plastic mono-arthritis, and in a case of hydrarthrosis there were no gonococci, but in a purulent arthritis the gonococci were found. In another, where the examination of the synovial liquid had shown no gonococci, a culture inoculated with the synovial fungosities gave a large number of colonies of gonococci. This has already been demonstrated by Burci, and shows that the microbe may die quickly in the synovia and remain localized in the solid tissues.

Permanganate of Potash in Local Tuberculosis.

Dr. Bayeux, a former house physician of the Paris hospitals, and who is well known for his work on diphtheria and intubation, has been advocating the use of permanganate of potash in suppurative lesions of tuberculous origin. On recent ulcerations he uses a concentrated 2 per cent. solution. Chronic abscesses are washed out three times a week with a 1 in 500 or a 1 in 1,000 solution. He also employs as dressing compresses dipped in 1 per 1,000 solution of permanganate of potash.

Operation for Cancer of the Esophagus.

Dr. J. L. Faure, surgeon at the Hotel Dieu, performed two or three weeks ago an operation for cancer of the esophagus, which, I believe, has never been undertaken before. The tumor was situated in the mediastinum, and the patient had already been operated on for gastrotomy and was in an emaciated condition. Dr. Faure began by making an incision in the anterior cervical region and liberating the esophagus, a catgut being placed around it. The patient was then turned over on the back, and an incision made between the right scapula and vertebral column. Five or six ribs were excised, including the first, and through the deep aperture thus made, the esophagus was dissected and removed. The patient died the next day. Dr. Faure is a clever operator; it is, however, a question whether the operation was justified by the condition of the patient.

Bad Bread in Paris.

Dr. de Lavarenne, the editor of the *Presse Médicale*, has recently published an article on the quality of the bread sold in Paris, in which he shows that the latter is far from nutritious and not easily digested. New methods have been discovered whereby the albuminous and fatty part of bread may be more readily retained, and by comparing the analysis of the two kinds of bread, one is struck by the following figures: Albuminous bodies, 10.25, as against 6.75. Fat, 5.02, as against 0.8, and dextrine, 10.61, as against 3.43. Mineral salts, 3.13, as against 0.4. These figures are quite convincing, and show how justified are the complaints which one so often hears in connection with this subject.

Importance of Medical Men in Politics.

It is a noteworthy fact that medical men play a much more important political rôle in continental countries than in either England or the United States. Such an illustrious example as Virchow illustrates this. In the French republic there are fully forty or fifty deputies who are physicians, and the minister of the interior, Dr. Combes, is a medical man. The president of the Swiss confederation, Deucher, is also a physician, and is about to begin his third term of office.

The Figaro's Sanatorium Subscription.

The *Figaro*, one of the most important French dailies, has just started a subscription list for the establishment of sanatoria for consumption, and already over a million francs have been contributed. Emma Calvé, the celebrated singer, has long furnished the funds for a sanatorium situated in the Aveyron a part of France from which she comes. This sanatorium is built for about forty girls from 6 to 12 years old suffering from some chronic disease. They are kept for about two months and then returned to their parents. Another well-known sanatorium for children has been established at Hendaye, on the southern coast of France, and is for scrofulous and tuberculous children.

Eichhorst's Opinion on the Treatment of Diabetes.

At a meeting held by the Medical Society of Zurich, Dr. Eichhorst gave an "exposé" of his ideas on the treatment of diabetes by drugs and mineral waters. Dr. Eichhorst has tried various drugs on patients who were either following their usual

regimen or else a special antidiabetic diet, and he has come to the conclusion that they were of no efficacy. The drugs employed were salicylic acid, salol (which has been recommended by Ebstein), phenic acid, antipyrin, and even mercury and the iodids when there was syphilis. As for the results obtained at Carlsbad and Neuenahr, they would be due to the strict mode of life followed. Dr. Eichhorst considers there is but one real treatment of diabetes, and that is the special diet. He never advocates changing the diet suddenly, as he has seen diabetic patients in whom the sudden suppression of farinaceous food has caused the appearance of acetone in the urine. He prefers that a diabetic patient should be in good condition and have a little sugar in the urine, rather than one who is growing thin and weak on account of too severe a diet. His patients are weighed regularly, as this is one of the best means of noting any change. He does not favor the use of alcohol, which can be advantageously replaced by various fats such as butter, cream, ham, cheese. Light tea or coffee are permissible. Eichhorst's treatment, therefore, consists in the progressive use of a special diet.

Too Many Physicians in France.

The *Temps*, the most important daily published in Paris, published an article recently on the number of physicians in France. Professor Debove, the dean of the Paris faculty, had said there were too many physicians in France, as quoted in THE JOURNAL last week, page 109. The author of the article in The *Temps* remarked that what was needed was to have good physicians, and not to create a special profession for those who are favored by fortune. Moreover, if one examines the list of great physicians in France, one does not find that many began life with a capital to fall back on. Professor Peter, for instance, was a journeyman printer, and to come to those of more recent fame, a well-known physician of the hospitals was formerly an employe of the Bon Marché, and a surgeon whose name is seen very often was a simple usher in a public school.

Smallpox at Nice in 1901-1902.

At a meeting of the Academy of Medicine, held December 16, Dr. St. Yves-Menard, the well-known vaccination specialist, read a report by Dr. Balestre on the recent epidemic of variola in Nice (1901-1902). There were 1575 cases and 549 deaths. The disease began in the poorer quarters, and the vaccination of the regiment quartered in the town had a good effect, there being fewer cases of contagion among the men than among the women.

There was a vacancy for a seat in the section of medical pathology, and Dr. Chauffard, who is specially known for his work on the liver, was chosen by 65 votes out of 75.

Correspondence.

Was It Beri-beri?

NEW YORK, Jan. 10, 1903.

To the Editor:—For the information of Dr. Frank Fenwick Young, whose interesting experiences with "Beri-beri in Louisiana" you have published in THE JOURNAL, kindly print the fact that beri-beri has been found on ships reaching this port, all with carbon-producing cargoes (sugar, graphite, burnt Java coffee, etc.), whose crews had as their dietary *no rice at all* for the entire voyage. Dr. Judson Daland also found such an outbreak of beri-beri, on a sugar ship, too, which reached Philadelphia, whose crew were Lascars; that is, pork eaters.

In an interesting investigation which I made many years ago with Col. John Screven of Savannah, Ga., the largest rice grower in the world, we found no beri-beri in those connected with the culture of rice, but plenty of malarial rheumatism (multiple neuritis, perhaps,) in those who did not take proper precautions while cultivating the flooded grounds. The feet of all rice cultivators are especially exposed to infections, but I did not find any of those who ate rice to have "multiple neuritis," or anything else that other people might not have had. Nor in Japan, where I treated thousands of rice cultivators from the province of Owamori (the farmers' province) there was no more beri-beri than in and about Tokio itself.

I have made a comparison of "Rice Culture in Japan, Mexico and the United States," which was published by the *Sei I Kwai*, some years back, in which I showed that the main danger from rice fields and rice culture was typhoid fever from human excrement, which was used as manure. Therefore, eating rice, even imperfectly cooked, could not produce beri-beri by itself; it would be accompanied by typhoid fever. But in the Orient all rice is most thoroughly cooked, which destroys every germ. If rice was, as diet *per se*, the cause of beri-beri, it should affect as well those who live on high grounds and mountains. Beri-beri never attacks even the higher wards of Tokio, which shows that the poison of beri-beri is heavier than air. Rice diet is not, therefore, the cause of beri-beri. Dr. Young will not find his "beri-beri" in those Louisianians who eat even nothing but rice and who live on high ground; that is, if the disease he describes is true beri-beri and not some foot infection. Beri-beri does not limit itself to "a radius of 20 miles," and could not have an outlined geographical limitation if it was due to the eating of rice. Beside this, there is no anemia, no fever in beri-beri. ALBERT S. ASHMEAD, M.D.

Method of Yellow Fever Transmission.

NEW ORLEANS, Jan. 7, 1903.

To the Editor:—In THE JOURNAL (Jan. 3, 1903, page 50) is a report of the discussion, at the recent session of the American Public Health Association, of the method of transmission of yellow fever. THE JOURNAL can not, of course, publish a full report of such a discussion, and the report published, therefore, must necessarily be incomplete and imperfect. Your reporter has placed me in a position which I do not desire to occupy. I am sure the error would ordinarily be considered a matter of small importance not worthy of correction, but my convictions on the subject of quarantine against yellow fever are so strong, and my interest in the subject so intense that I beg the privilege of correcting your report in so far as it refers to myself.

What I said was that "Quarantine should be *most* strenuous against that which has been *proven* infectious even at the expense, if necessary, of those measures employed against that which is only *suspected;* where measures against both fomites and mosquitoes can be operated no valid excuse can be urged for neglecting the mosquitoes."

The idea intended to be conveyed was that quarantine against yellow fever *should be* what it *was not*. While the treatment for fomites in transportation may or may not be important, the treatment for mosquitoes undoubtedly is of the greatest importance, and should be given the highest consideration by quarantine authorities. To neglect the obvious application of the mosquito theory to quarantine practice is an unpardonable mistake. Whether or not fomites may convey the disease, the quarantine of the future to be efficient against yellow fever *must* afford protection against the mosquito.

Respectfully, QUITMAN KOHNKE, M.D.,
Health Officer of the City of New Orleans.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

DOES NOT ENDORSE GOAT LYMPH COMPANY.

PHILADELPHIA, Dec. 31, 1902.

To the Editor:—You will greatly oblige me by stating in your columns that the endorsement by me set forth in the circular of the Goat Lymph Sanitarium Association of Chicago, is fictitious, and any mention of my name in connection with the enterprise, is entirely unauthorized. ALBERT MCCONAGHY.

RELATIONS OF DIAMETERS IN O. L. A. POSITION.

Dec. 22, 1902.

To the Editor:—Please mention in your query column what diameters of the fetal skull are engaged in the oblique diameters of the pelvis in L. O. A. cases. Y.

ANS.—When the head is O. L. A. and in moderate flexion, the occipito-frontal diameter lies in the right oblique diameter of the pelvis. The biparietal diameter of the head which lies at right angle to the occipito-frontal does not lie in the left oblique because the two oblique diameters of the pelvis do not cross at right angles.

With moderate flexion and synclitism the diameter of the head which lies in the left oblique of the pelvis is one that passes from the left parietal protuberance (or boss) through the right frontal protuberance (or boss).

Marriages.

WILLIAM RUPP, M.D., to Miss Eleanor M. Turner, both of Chicago, Dec. 24, 1902.

HARRY W. WARDLE, M.D., to Miss Helen Prince, both of Chicago, Dec. 25, 1902.

PATRICK J. MURRAY, M.D., to Miss Mary F. Murray, both of Brooklyn, Dec. 30, 1902.

EUGENE CLOWER, M.D., Moultrie, Ga., to Miss Pearl Wight of Cairo, Ga., January 7.

C. G. HOLLAND, M.D., to Mrs. Dan Franklin, both of Newport, Tenn., Dec. 16, 1902.

PAUL S. SCHOLES, M.D., to Miss Bertha Chapman, both of Canton, Ill., Oct. 15, 1902.

JAMES J. BURCH, M.D., to Miss Lula Bussey, both of Double Branches, Ga., Dec. 23, 1902.

T. E. BRADLEY, M.D., Nashville, Ga., to Miss May Combs of Adairsville, Ga., Dec. 30, 1902.

OSCAR N. CARTER, M.D., to Miss Annie Laura Hosey, both of Brookline, Mo., Dec. 24, 1902.

JOHN M. NEELY, M.D., Elmwood, Neb., to Miss Edna Perry of Ashland, Neb., Dec. 30, 1902.

SMITH HOLLINS MCKIM, M.D., to Miss Margaret Emerson, both of Baltimore, Dec. 30, 1902.

HANSELL CRENSHAW, M.D., to Miss Carolyn Proctor Ollinger, both of Atlanta, Ga., January 1.

FRANK B. MAYNARD, M.D., to Miss Emma Marie Lester, both of Rochester, N. Y., Dec. 17, 1902.

JAMES G. HARRISON, M.D., to Miss Lillian Middlebrooks, both of Sparta, Ga., Dec. 17, 1902.

A. WALTER JONES, M.D., to Miss Vida Luena Wingerter, both of Akron, Ohio, Dec. 31, 1902.

CLYDE O. DONALDSON, M.D., to Miss Nettye W. Burns, both of Kansas City, Mo., Dec. 17, 1902.

FREDERICK S. HAEBERLE, M.D., St. Louis, to Miss Helen Carter of Nashville, Ill., Dec. 17, 1902.

ARNE OFTEDAL, M.D., Bisbee, N. D., to Miss Josephine Olson, at Cando, N. D., Dec. 10, 1902.

DUNCAN C. MCLEAN, M.D., Deckerville, Mich., to Miss Libbie McNair of Worth, Mich., Dec. 18, 1902.

OSCAR B. BELLER, M.D., Garrison, Iowa, to Miss Alfreda Stocker of Vinton, Iowa, Dec. 30, 1902.

JOHN VINCENT LITTIG, M.D., to Miss Bessie Barr Cassell, both of Davenport, Iowa, Dec. 17, 1902.

LAWRENCE B. COHNE, M.D., Baltimore, to Miss Becky Esther Bernstein of New York City, Dec. 16, 1902.

THOMAS PINCKNEY WARING, M.D., to Miss Martha Gallaudet Backus, both of Savannah, Ga., Dec. 24, 1902.

GEORGE F. POTTRIGER, M.D., Hamburg, Pa., to Miss Florence L. Ritter of West Reading, Pa., Dec. 28, 1902.

HARVEY BURTON UPCHURCH, M.D., Carrollton, Ala., to Miss Mary Edna Spragins of Jackson, Tenn., January 7.

HARRY SHERWOOD ALLEN, M.D., Gallipolis, Ohio, to Miss Alma Roberts Thomas of Ironton, Ohio, Dec. 30, 1902.

JULIUS STERLING LOOMIS, M.D., South Windsor, Conn., to Miss Nellie Bean of New Haven, Conn., Dec. 24, 1902.

EDWIN J. CHAMBERLAIN, M.D., Grand Rapids, Mich., to Miss Margaret d'Hays Walker of Louisville, Ky., Dec. 31, 1902.

GEORGE T. DRENNON, M.D., Clarksville, Tenn., to Miss Cyrenne Stephens of Thompson Creek, Tenn., Dec. 17, 1902.

ELBERT LOGAN WRIGHT, M.D., Parkersburg, W. Va., to Mrs. Anna Dusenberry of Buffalo, N. Y., at Parkersburg, W. Va., Dec. 16, 1902.

Deaths.

Irving S. Vallandingham, M.D. University of Maryland, Baltimore, 1862, died at his home in Middletown, Del., Dec. 30, 1902, aged 62. He served in the Confederate Army as assistant surgeon, and had been a member of the State Board of Health, secretary of the State Medical Council and a trustee of Delaware College, and was a member of the American Medical Association.

Julius Kohl, M.D. St. Louis Medical College, 1859, a member of the American Medical Association, formerly a member of the Illinois State Board of Health, and for 36 years a resident of Belleville, Ill., died at his home in that city, January 4, from a cancer of the stomach, after a long illness, aged 64.

Henry H. Howland, M.D. University of the City of New York, 1878, a member of the American Medical Association, and at one time a prominent laryngologist of Denver, died instantly in that city as the result of a self-inflicted gunshot wound, while despondent from ill health, Dec. 27, 1902, aged 53.

Marcus A. Bogie, M.D. Long Island College Hospital, Brooklyn, N. Y., 1864, chief surgeon of the Kansas City Belt Railway and a member of the International Association of Railway Surgeons, died at his home in Kansas City, January 4, from apoplexy, after an illness of two days, aged 62.

Colin A. McPhail, M.D. Trinity Medical College, Toronto, 1892, vice-president for Prince Edward Island of the Canadian Medical Association and treasurer of the Maritime Medical Association, died suddenly at his home in Summerside, Dec. 3, 1902, from apoplexy, aged 39.

Charles Edmond Chase, M.D. University of Vermont, Burlington, 1873, president of the Middlesex East District Branch of the Massachusetts Medical Society, died at his home in Woburn, Mass., Dec. 26, 1902, after a lingering illness, from Bright's disease, aged 53.

Henry Van Ostrand, M.D. Geneva (N. Y.) Medical College, 1843, assistant surgeon to the First Michigan Engineers and Mechanics during the last two years of the Civil War, died at his home in Yankton, S. D., Dec. 26, 1902, after an illness of about one year, aged 84.

John B. Amiss, M.D. New York University, 1858, a member of the National Association of Railway Surgeons, and local surgeon of the B. and O. Ry., at Harrisonburg, Va., died suddenly at his home in that place, January 4, from angina pectoris, aged 68.

William C. Gallagher, M.D. Bellevue Hospital Medical College, New York, 1886, for several years on the house staff of St. Francis' Hospital, New York City, died at the New York Hospital, January 5, from typhoid fever, after an illness of nine weeks, aged 40.

Byron Chapman, M.D. Western Reserve University, Cleveland, 1847, a member of the American Medical Association and a pioneer citizen and practitioner of Summit County, Ohio, died at his home in Copley, Dec. 6, 1902, after an illness of six days, aged 81.

Ralph Brooks, M.D. University of Pennsylvania, Philadelphia, 1897, first assistant physician at the National Soldiers' Home, Hampton, Va., died in the hospital of that institution, January 4, five days after an operation for appendicitis, aged 27.

Robert E. Williams, M.D., late captain and assistant surgeon, U. S. V., University of Georgetown, Washington, D. C., 1870, died at the U. S. General Hospital, Presidio of San Francisco, from cirrhosis of the liver, Dec. 30, 1902, aged 58.

Charles A. Osborne, M.D. Buffalo Medical College, surgeon of the Eleventh Michigan Cavalry in the Civil War, died at his home in Owosso, Mich., January 2, from paralysis, after a long period of invalidism, aged 70.

Lewis P. Wheat, M.D. Medical College of Virginia, Richmond, 1881, died at his home in that city from heart disease, Dec. 29, 1902, after a short illness, aged 42. He was formerly assistant to Dr. Hunter McGuire.

Alexander Young Scott, M.D. Trinity Medical College, Toronto, 1887, died suddenly, January 3, at his home in Toronto, from myocarditis following an attack of typhoid fever two years before, aged 41.

James Beahan, M.D. Jefferson Medical College, Philadelphia, 1852, who had been out of health for a long time, died at his home in Rochester, N. Y., January 3, from the effects of a fall two weeks before, aged 80.

Nesbitt Frederick Jordan, M.D. Medical College of Ohio, Cincinnati, 1884, died at his home in Bloomington, Ill., Dec. 28, 1902, from pneumonia following typhoid fever, after an illness of four weeks, aged 45.

C. W. Hopkins, M.D. McGill University, Montreal, 1901, medical superintendent of the Montreal Maternity Hospital, died, Dec. 28, 1902, in that city from typhoid fever, after an illness of five weeks.

William H. Haviland, M.D. Starling Medical College, Columbus, Ohio, 1889, died at his home in Columbus, Dec. 30, 1902, from tuberculosis, after an illness of eighteen months, aged 38.

Charles J. Bell, professor of chemistry in the University of Minnesota medical department, Minneapolis, died at Somerville, Mass., January 4, from Bright's disease, aged 48.

Waldo E. Clark, M.D. Detroit College of Medicine, 1887, is supposed to have committed suicide by drowning, Dec. 29, 1902, aged 45. His body was found in the ice at Saginaw, January 6.

Harrison S. Walrath, M.D. College of Physicians and Surgeons, Chicago, 1883, an invalid for many months, died suddenly at his home in St. Paul, Minn., Dec. 21, 1902, aged 60.

Charles H. Black, M.D. Jefferson Medical College, Philadelphia, 1875, died at his home in Turtle Creek, Pa., January 2, from stomach trouble after an illness of ten weeks, aged 53.

Sherburne Choppin, M.D. Tulane University, New Orleans, 1886, died from pneumonia in the Charity Hospital, New Orleans, Dec. 30, 1902, after an illness of eleven days, aged 44.

Louis Charette, M.D. Albany (N. Y.) Medical College, 1852, who retired from practice in 1895, died at his home in Glens Falls, N. Y., from gastroenteritis, Dec. 26, 1902, aged 87.

Allen George Berry, M.D. Kentucky School of Medicine, Louisville, 1886, died at his home in Ashland, Ky., from tuberculosis, after a long illness, Dec. 30, 1902, aged 43.

Charles W. Hedges, M.D. Vanderbilt University, Nashville, Tenn., 1901, died at his home in Newkirk, Okla., Dec. 21, 1902, ten days after an operation for appendicitis, aged 26.

Ralph G. Morgan, M.D. Medical College of Indiana, Indianapolis, 1898, died at his home in that city, January 1, from peritonitis, after an illness of two weeks, aged 29.

D. B. Hall, M.D. University of Michigan, Ann Arbor, one of the earliest graduates of that institution, died recently, aged 75, and was buried at Ithaca, Mich., Dec. 24, 1902.

John Emil Palmquist, M.D. University of Minnesota, Minneapolis, 1896, died from tuberculosis at his home in Holdredge, Neb., Dec. 21, 1902, after a long illness, aged 32.

John Stevens, M.D., Philadelphia, 1872, the oldest practitioner of Bangor, Me., died at his home in that city from dilatation of the heart, Dec. 21, 1902, aged 67.

William E. Brownell, M.D. New York University, 1879, died at his home in New Bedford, Mass., Dec. 27, 1902, from uremia, after an illness of nine days, aged 45.

James H. Lowe, M.D., Philadelphia, for many years a practitioner of New York City and Atlanta, Ga., died at his home in the latter city, January 2, aged 82.

William Scott White, M.D. University of Virginia, Charlottesville, 1875, died at his home in Lexington, Va., Dec. 29, 1902, from Bright's disease, aged about 50.

William Scott, M.D. University of Virginia, Charlottesville, died at his home in Lexington, Va., after a long illness, from Bright's Disease, Dec. 29, 1902, aged 50.

L. E. Towne, M.D. Rush Medical College, Chicago, 1868, died at his home in Broadhead, Wis., January 6, from paralysis, after an illness of two years, aged 76.

Schuyler F. Shidler, M.D. College of Physicians and Surgeons, Chicago, 1888, died a few hours after a fall from his horse, near Sheridan, Mo., January 3.

Carl Schumacher, M.D. Cleveland University of Medicine and Surgery, 1883, died at his home in Syracuse, N. Y., after an illness of nine months, January 3.

H. S. Osborn, M.D. Cincinnati Medical College, for many years a practitioner of Bozeman, Mont., died at Denver, Nov. 22, 1902, after a long illness, aged 80.

Daniel P. Buckey, M.D. Baltimore Medical College, 1894, Flemington, W. Va., was run over by a train and instantly killed at Flemington, Dec. 29, 1902.

Angus C. McDonnell, M.D. McGill University, Montreal, 1852, one of the leading physicians of Montreal, died from pneumonia, January 2, aged 74.

Robert G. Petway, M.D. Nashville (Tenn.) Medical College, 1855, died suddenly from heart disease at his home in Nashville, Dec. 24, 1902, aged 68.

Charles S. Hoover, M.D. University of Maryland, Baltimore, 1884, was found dead, January 4, in his office in Ottawa, Ill., from an overdose of cocain.

Simon M. Landis, M.D. American College of Medicine in Pennsylvania, Philadelphia, 1854, died at his home in Boston, Mass., Dec. 25, 1902, aged 73.

William C. Cole, M.D. New York University, 1843, died at his home in Van Wert, Ohio, January 1. He served through the Civil War as surgeon.

William H. Middleton, M.D. Washington University, St. Louis, 1866, died at his home in Camden Point, Mo., after a long illness, Dec. 25, 1902.

James E. DeWolf, M.D. Harvard University, Boston, 1866, died suddenly at his home near Baraboo, Wis., from heart disease, January 5, aged 60.

Joseph Huff, M.D. Western Pennsylvania Medical College, Pittsburg, 1901, died from smallpox at the Municipal Hospital, Pittsburg, Dec. 30, 1902.

J. Henry Rider, M.D. Missouri Medical College, St. Louis, 1870, died from pneumonia at his home in Cape Girardeau, Mo., Dec. 23, 1902, aged 61.

T. L. Webb, M.D. Georgia College of Eclectic Medicine and Surgery, 1889, died at his home in Cookeville, Tenn., Dec. 24, 1902, aged about 50.

J. W. Summers, M.D., an old practitioner of Cameron, S. C., died at his home in that place, after a long illness, Dec. 28, 1902, aged 65.

Ernest W. Bradley, M.D. Hahnemann Medical College, Chicago, 1879, died suddenly, Dec. 28, 1902, at Grass Valley, Cal., aged 48.

W. W. Watkins, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1882, died at his home in Carthage, Mo., January 2, aged 75.

Ephraim W. Gantt, M.D. College of Physicians and Surgeons, New York, died at his home in Lockport, N. Y., January 5, aged 72.

William J. Deane, M.D. University of Buffalo, N. Y., 1895, of Buffalo, died at Kingston, Dec. 31, 1902, from tuberculosis, aged 36.

H. Van Gerhart, M.D. Missouri Medical College, St. Louis, died in San Diego, Cal., Dec. 28, 1902, from heart disease, aged 29.

William R. Grove, M.D. University of Maryland, Baltimore, 1865, died at his home in Columbia, Pa., January 3, aged 65.

William L. Dennison, M.D. Detroit College of Medicine, 1894, died at his home in Clarkston, Mich., Dec. 28, 1902, aged 30.

James T. Scott, M.D. Missouri Medical College, St. Louis, 1854, died at his home in Paynesville, Mo., Dec. 28, 1902, aged 70.

William Bevier, M.D. Eclectic Medical Institute, Cincinnati, 1852, died at his home in Waterloo, Ind., Dec. 29, 1902, aged 80.

William A. Looney, M.D. Rush Medical College, Chicago, 1868, died at his home in Vienna, Ill., January 5, aged 74.

William R. Freeman, M.D. University of Nashville, Tenn., 1871, died at his home in Bellbuckle, Tenn., January 1.

J. J. Arendale, M.D. University of Tennessee, Nashville, 1894, was shot and killed at Waller, Texas, January 5.

David Jacobson, M.D. New York University, 1887, died, Dec. 31, 1902, at his home in New York City, aged 38.

D. D. Davisson, M.D., the oldest practitioner of Madison County, Iowa, died recently at Winterset.

Arthur J. Padron, M.D., died at his home in New Orleans, Dec. 30, 1902, after a lingering illness.

Miscellany.

Blue Toes.—Dr. Arthur Hall, Sheffield, England, has described cases of blue toes which at first were completely baffling to all attempts to learn their cause. It was found that acid perspiration decomposed the black dye of the stockings. The discoloration appeared between the toes. In another case a woman who wore a dark purple blouse had discoloration of the axillæ, while the arms and parts of the body in contact with the blouse were uncolored. These facts led to the suspecting the dye and proving it to be, in connection with the sweat, the source of the phenomenon.

Official Warning Against Charlatans.—The local board of health of Carlsruhe has issued two official announcements warning against a certain herb doctor who has been advertising in the lay press and an electric institute advertised to cure all kinds of diseases. The warning states that it is

impossible for the herb doctor to make a correct diagnosis by letter, as he claims, and that his tea, liqueur and ointment have no curative value, while they cost twice as much as a physician's advice and prescription. As his practices defraud suffering persons the board urgently warns against applying to the herb doctor in question. The electric institute, it also explains, was at first under the supervision of a regular physician, but he has retired, and the proprietor, originally a butcher, is now in charge.

End of Garnault's Experiment.—THE JOURNAL has mentioned Garnault's two inoculations of his arm with fragments from a tuberculous lesion in the liver of a cow with advanced tuberculosis. Indurated nodules developed at the points inoculated, and the pus contained tubercle bacilli virulent for guinea-pigs for several months. Garnault thinks that he has established his contention that bovine tuberculosis inoculated into man will produce human tuberculosis. He therefore considers the experiment at an end and has had Tuffier extirpate the nodules. They were examined at the Pasteur Institute and found to be typical specimens of local tuberculosis, restricted to the points inoculated. Garnault is exceptionally robust, free from the slightest tuberculous antecedents, inherited or acquired, and he ingested 400 gm. of raw meat every day during the experiment. He is convinced that the inoculation would have induced general tuberculosis in a less resistant subject. No virulent bacilli were found after September at the points inoculated in June, but the bacilli were still virulent in the nodules inoculated in July. No reference was made to his experience at the recent Tuberculosis Conference except Koch's general statement that the local tuberculous lesions observed occasionally on persons handling bovine tuberculous material, were arguments against the transmission of bovine tuberculosis to man, as they are never followed by general infection, but always remain a mere circumscribed lesion, becoming more and more attenuated and gradually healing in time. Garnault's communications have been published in the *Gaz. Med. de Paris*.

The State Board and the Ohio Medical Colleges.—The *Cleveland Medical Journal* says editorially in its December number: The *Eclectic Medical Journal*, of Cincinnati, in its November issue publishes an editorial entitled "A Wrong to Ohio Colleges." By this caption it denotes the action of our State Board of Medical Registration and Examination in adding a little history, a little mathematics and a little English to the requirements for admission to the medical colleges of the state. It joins hands with the *Lancet-Clinic* in the effort to keep the educational standard of our profession at as low a notch as seems compatible with the well-recognized general professional demand for a high standard. The increase in required studies made by the board is too slight to justify the strong language of the two Cincinnati objectors. In a discussion of this sort it is well to lay bare the real facts at issue. The *Eclectic Medical Journal* is owned by the Scudder Brothers Company, who are also proprietors of the Eclectic Medical Institute of Cincinnati. This college, along with the other medical schools in Cincinnati, has felt keenly the effect of the raised entrance standard required by the present medical-practice act. This is, however, the first convenient opportunity for a public expression of alarm at diminishing classes. "It's the galled jade that winces." When the profession demanded a higher standard it knew very well that the medical colleges were to suffer, because we all knew that there were too many in the state and that they were graduating ill-prepared physicians. That the process now going on is painful for the colleges none can deny, but the profession can only point to the record of the colleges' own failure generally and materially to improve educational conditions. It is evident, too, that Cincinnati colleges have suffered more promptly from the raised standards, for the reason that their former large southern student clientele has been driven to the less exacting Louisville schools. Very fortunately the question is not at all one of therapeutic "schools," as the regular profession is in a minority on the state board. All this shows clearly enough to the disinterested observer that the rank and file of all branches of the profession favor a high educational standard, while many of those connected with the schools feel themselves compelled to adopt a different attitude. Nor is any question of intellectual or moral dishonesty involved—it is merely natural self-interest. However, the logic of the situation is evident and inexorable. There must be fewer schools. It is "up to" the colleges to determine how the reduction in number shall take place, and in Cleveland the problem is now practically solved. For years we have had too many colleges in Ohio, and it was expected that when the profession demanded a reduction there would be some shrieks of pain—and now we have them.

Book Notices.

THE PHYSICIAN'S POCKET ACCOUNT BOOK, Consisting of a Manila-Bound Book of 208 Pages and a Leather Case. By J. J. Taylor, M.D. Price, $1.00 Complete. Subsequent Books to Fill the Case 40 Cents Each, or 3 for $1.00. Philadelphia: Published by The Medical Council.

This is strictly a business account book without the obstetric tables, tables of poisons, etc., which are common in these publications. It is well arranged and convenient. The business suggestions in the first part of the work are the only printed matter and these are useful and suggestive. The book is arranged in a sort of single-entry ledger form, without dates, so that it is good for all time.

ATLAS AND EPITOME OF ABDOMINAL HERNIAS. By Privatdocent Dr. Georg Sultan of Göttingen. Edited, with Additions, by William B. Coley, M.D., Clinical Lecturer on Surgery, Columbia University (College of Physicians and Surgeons). With 119 Illustrations, 36 of Them in Colors, and 277 Pages of Text. Cloth. Price, $3.00 net. Philadelphia and London: W. B. Saunders & Co. 1902.

This little book belongs to the Saunders' series of atlases, and is a translation from the German. The text does not profess to be exhaustive, but it is clear and concise, and the common varieties of hernia are well described. The editor has added an occasional note to the text. One, condemning the injection method of treating hernia, and another condemning the use of buried non-absorbable suture materials in the radical operation, are to be commended. Since the mortality of the radical operation is only 0.5 per cent. (5,418 cases, 28 deaths), and the recurrences only about 4 per cent. (2,853 cases, 114 recurrences), there is little reason why the ordinary individual should be burdened with the wearing of a truss. The illustrations, many of them in colors, are works of art and are the chief value of the work. Post-operative ventral hernia has received no attention, and the method of operating on umbilical hernia by overlapping from above downward, as has been so satisfactorily practiced of late by some American operators, has not been mentioned.

ATLAS AND EPITOME OF TRAUMATIC FRACTURES AND DISLOCATIONS. By Professor Dr. H. Helferich, Professor of Surgery at the Royal University, Greifswald, Prussia. Edited, with Additions, by Joseph C. Bloodgood, M.D., Associate in Surgery, Johns Hopkins University, Baltimore. From the Fifth Revised and Enlarged German Edition. With 216 Colored Illustrations on 64 Lithographic Plates, 190 Text-Cuts, and 353 Pages of Text. Cloth. Price, $3.00 net. Philadelphia and London: W. B. Saunders & Co. 1902.

The chief point to be said in favor of this work are the colored plates and illustrations, as the text is little more than a setting for the plates. However, many excellent little points will be found scattered through the text, as, for instance, the condemnation, as a rule, of the primary permanent fixed dressing; the dangers and advantages of the ambulatory treatment, etc. The editor has added a number of notes, most of which are good, but at times he is too positive, as, for instance, the statement that "The functional result of a proper resection of these joints (shoulder and elbow) is always excellent," and in operative reduction of old dislocations of the shoulder, "Even in cases in which perfect reduction is possible, ... the function of the arm is never as good as after a resection." Again, under dislocations of the hip we find the statement, "In very old cases all hope of obtaining a movable joint must be abandoned, and a resection or a subtrochanteric osteotomy performed to correct the position of the limb." There are a number of cases on record where a very good movable joint has been obtained after operative reduction of old dislocated hips. While the work can not take the place of the more extensive treatises on fractures and dislocations, still the plates give to it a distinct value.

MANUAL OF GYNECOLOGY. By Henry T. Byford, M.D., Professor of Gynecology and Clinical Gynecology in the College of Physicians and Surgeons of Chicago. Third Revised Edition. Containing 363 Illustrations, Many of Which Are Original. Cloth. Pp. 598. Price, $3.00 net. Philadelphia: P. Blakiston's Son & Co. 1902.

The subjects in this work are arranged in the order followed by the author in his lectures. The wording, paragraphing, marginal notes, etc., all indicate, as is stated in the preface, that the work is primarily intended for the student. The chapter on cystitis is very primitive, and such terms as "spurious cystitis" should be avoided by a teacher. Under lacerations of the perineum we find hardly any mention of laceration of the muscles forming the true pelvic floor, and no reference is made to any of the modern operations on these muscles. The subject of gonorrheal infection is clearly handled, but the statement that "gonorrhea always begins as an acute inflammation" in the female can not be sustained. The advice to transfuse salt solution in the collapse of ruptured extra-uterine pregnancy before the bleeding points have been secured is dangerous, because if the hemorrhage has temporarily ceased, the increased tension produced by the salt solution may cause its renewal. The treatment of many questions on pathology would not stand a critical review, but as the subjects are not entered into extensively, but are more to give the student a general idea, their treatment answers the purpose. As a student's reference book it will continue to hold a leading place.

DICTIONARY OF PHYSIOLOGY AND PSYCHOLOGY. Including Many of the Principal Conceptions of Ethics, Logic, Esthetics, Philosophy of Religion, Mental Pathology, Anthropology, Biology, Neurology, Physiology, Economics, Political and Social Philosophy, Philology, Physical Science and Education, and giving a Terminology in English, French, German and Italian. Written by Many Hands and Edited by James Mark Baldwin, Ph.D. (Princeton), Hon. D.Sc. (Oxon.), Hon. LL.D. (Glasgow), Stuart Professor in Princeton University. With the Coöperation and Assistance of an International Board of Consulting Editors. In Three Volumes, with Illustrations and Extensive Bibliographies. Vol. II. Cloth. Pp. 892. Price, $5.00. New York and London: Macmillan & Co., Ltd. 1902.

The second volume of Baldwin's great dictionary of philosophy and psychology is considerably more bulky than the first and maintains well the character and general excellence and fulness that were so noticeable in the earlier published portion. There are very few things which we looked for and failed to find; the omissions were the more notable for their rarity. We find, however, by close searching here and there, an oversight, such as is inevitable in any work of this kind; thus, among modern Italian philosophers we see no mention of Rosmini, for example, who has not received a biographical note. Such omissions, however, are very few and the book will be a most valuable work of reference and of study to the professional man who takes an interest in the more abstruse problems of his work. The various articles on mental diseases and other medical subjects in this volume are excellent. This book completes the text of the work, which, however, will not be complete for the student without the coming volume containing the bibliography. The work as a whole fills most satisfactorily a long-existing gap in our literature.

Societies.

Chatham County (Ga.) Medical Society.—This society was incorporated Dec. 12, 1902. The objects are the advancement of medical science, social culture and the promotion of a high standard of ethics among its members.

Marion County (Ohio) Medical Society.—At the regular annual meeting of this society, held January 6, at Marion, the following officers for the ensuing year were duly elected: President, Dr. Oliver W. Weeks (re-elected); vice-president, Dr. Robert Ramroth; secretary Dr. Herman S. Rhu; treasurer, Dr. Francis B. Sawyer, all of Marion; and board of censors, Drs. Lewis D. Hamilton, and Elmer O. Richardson, Marion, and Dr. John I. King, Martel.

New York Academy of Medicine.—The newly-elected officers of the academy are as follows: President, Dr. Andrew H. Smith; vice-president, Dr. M. Allen Starr; treasurer, Dr. Herman L. Collyer; trustee, Dr. Arthur M. Jacobus; member of committee on admissions, Dr. J. Milton Mabbott, and member of committee on library, Dr. Joseph Collins. The newly-elected officers of the Section on Pediatrics are Dr. Henry Heiman, president, and Dr. Linnæus E. La Fétra, secretary.

Columbus and Franklin County (Ohio) Medical Society.—At the meeting of the Columbus Academy of Medicine, Dec. 1, 1902, a new constitution and by-laws were adopted, which provide that the society shall embrace Franklin County and that in the future its relations with state and national medical societies shall be closer. At the annual meeting, Dec. 15, 1902, Dr. Francis W. Blake was elected president; Dr. Hugh Hendrixson, vice-president; Dr. John D. Dunham, secretary, and Dr. William C. Davis, treasurer, all of Columbus.

Canton (Ohio) Medical Society.—This society held its third annual banquet January 9, covers being laid for 100. Dr. Dan Milliken of Hamilton, Ohio, made the chief address. The officers elected for the ensuing year are: President, Dr. Allen B. Smith; vice-president, Dr. Frank E. Hart; corresponding secretary, Dr. D. F. Danker; recording secretary, Dr. Harry A. March; treasurer, Dr. Frank DaHinden; censors, Drs. James Fraunfelter, Odo E. Portmann, and Austin C. Brant. The society is in an exceedingly prosperous condition, and has been granted an alcove room in the Carnegie Library in process of construction.

Boulder County (Colo.) Medical Society.—This society held its annual meeting in Boulder, January 1. The retiring president, Dr. Emley B. Queal, Boulder, delivered the annual address on "Gastric Digestion," in which he reviewed the recent studies on the subject, as carried out by means of the *x*-rays and subnitrate of bismuth. The following officers were elected for the ensuing year: President, Dr. Emley B. Queal; vice-president, Dr. Oscar M. Gilbert; secretary, Dr. W. W. Reed, and treasurer, Dr. Martin E. Miles; censors, Drs. George H. Cattermole, Lafayette Z. Coman, and Oscar M. Gilbert, and delegate to the state society, Dr. George H. Cattermole, all of Boulder.

Academy of Medicine of Toledo and Lucas County, Ohio.—This society, January 9, completed its list of officers as follows: President, Dr. Julius H. Jacobson; vice-president, Dr. Samuel S. Thorn; secretary, Dr. Herbert E. Smead; financial secretary, Dr. Charles P. Wagar; treasurer, Dr. Willis W. Grube; board of censors, Drs. William H. Fisher, Oscar Hasencamp, William J. Gillette, John A. Wright, and Seth W. Beckwith; members library board, Drs. Samuel S. Thorn, Harrison Hathaway, William J. Gillette, Park L. Myers and A. L. Steinfeld, and committee on legislation and public health; Drs. William C. Chapman, Charles L. Van Pelt and William G. Dice, all of Toledo.

Association of College Gymnasium Directors.—This association held its sixth annual meeting in New York City, December 30 and 31. An interesting feature of the proceedings was the presentation by Dr. J. E. Raycroft, Chicago University, of a plaster model, one-quarter life size, representing the average American college athlete. This statuette was modeled from data obtained from the records of 400 athletes in the gymnasiums of Harvard, Yale, Cornell, Columbia and elsewhere. A significant fact was that this composite figure showed no abnormal display of muscle, but a good all-round development. Dr. W. A. Lambeth, of the University of Virginia, urged that the physical work done by college students should be credited to them just as the other work of the curriculum. Considerable time was given to the question of fatigue and overexertion in physical culture. Dr. R. T. McKenzie, McGill University, read a paper on the "Effects of Overexertion in Athletics and Gymnasium," and Dr. W. G. Anderson, Yale University, dwelt at great length on what had been accomplished toward determining when overexertion begins. The following officers were elected: President, Dr. Watson L. Savage, Columbia University; vice-presidents, Drs. Jay W. Seaver and W. A. Lambeth, Virginia; secretary-treasurer, Dr. James A. Babbitt, Haverford College. The next meeting will be held Dec. 31, 1903, at Princeton University.

SOUTHERN COLORADO MEDICAL ASSOCIATION.

Second Annual Meeting, held at Colorado Springs, Dec. 2 and 3, 1902.

The President, Dr. W. A. Campbell, Colorado Springs, in the Chair.

Among the papers read were the following: "Prostatectomy," by Dr. R. K. Hutchins of Colorado Springs.

DR. GEORGE F. LIBBY, Colorado Springs, read a report of a case of monocular blindness of fifty years' duration, with restoration of sight following hemiplegia. This case showed the influence of disease or injury of one part of the body on another organ or part of the body. Dr. Libby thought the blindness was psychic.

DR. GILLETT, Colorado Springs, read a paper on the "Medical Embryo from Conception to Inception," giving an outline of the embryo physician from start to finish.

A paper was read by Dr. Epler, Pueblo, on "Diseases of the Rectum." All these papers were freely discussed.

DR. M. BESHOAR, Trinidad, read a very interesting paper on the "Treatment of Typhoid Fever," giving his experiences of nearly fifty years' practice. This paper was thoroughly discussed and many new ideas were brought out.

DR. A. T. STODDARD, Pueblo, read a paper on "Diagnosis and Pathology of Pelvic Inflammations."

DR. DENNIS, Colorado Springs, read a paper on "Anesthetics and Anesthetizer."

A paper by Dr. J. W. Rambo, Florence, on "What Are We Prescribing for Our Patients?" showed how easy it is for physicians to get into a routine of prescribing and use the proprietary medicines and even nostrums.

The President's address was on "Colorado Climate and Eastern Patients." This paper was full of good ideas and bright things.

DR. W. A. SWAN, Colorado Springs, reported a case of rupture of the membranes two months before delivery; twins, males, breathing feebly for a few minutes, with a common membrane and two sacs. The mother made a slow recovery. In the discussion which followed many reported cases of rupture of membranes which were carried to full term or nearly so.

DR. H. W. HOAGLAND, Colorado Springs, reported a most interesting case of "General Secondary Carcinoma."

DR. SOLLY, Colorado Springs, delivered an address on the relation of rhinology to general medicine.

DR. A. C. MAGRUDER, Cripple Creek, showed a splint of his own devising for holding in apposition a fracture below the knee when putting on splint, wiring ununited bones, putting on plaster splint, or, in fact, in adjusting any apparatus or moving patient from place of injury to hospital or home without pain.

Membership Open to the Whole State.

A resolution was introduced by the President, changing the limit of membership to any part of the state, as follows:

WHEREAS, Our society bears the name of "The Southern Colorado Medical Association," which name leads many physicians of the state to believe that its membership is to be limited to those living south of the Great Divide, and

WHEREAS, There are a considerable number of physicians in the southern part of the state who believe our association is beneficial to them in many ways, and does not at all interfere with the meetings of the state society, but, on the contrary, is a benefit to the same in holding the profession together and providing an autumn meeting for them where they can meet, interchange experiences and mingle socially, and thereby throw off the responsibilities of practice in a degree.

Be It Resolved, That we accept membership from all sections of the state, and invite co-operation of the profession throughout the state in making the autumn meeting a success.

New Officers.

The list of officers for the ensuing year is as follows: President, Dr. Michael Beshoar, Trinidad; vice-presidents, Drs. Alexander C. Magruder, Cripple Creek, and Rutherford H. Paxton, Florence; treasurer, Dr. John A. Black, Pueblo, and secretary, Dr. Cyrus F. Taylor, Pueblo.

The society adjourned to meet at Cripple Creek Oct. 20, 1903.

WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Twelfth Annual Meeting, held at St. Joseph, Mo., Dec. 29 and -30, 1902.

The President, Dr. James E. Moore, Minneapolis, in the Chair.

(Concluded from page 119.)

Lung Surgery—Historical and Experimental.

DR. B. MERRILL RICKETTS, Cincinnati, discussed this subject and illustrated his remarks with a series of stereopticon views.

The Pathology that Remains After the Non-Surgical Treatment of Peritonitis.

DR. H. D. NILES, Salt Lake City, stated that 95 per cent. of all survivors of non-surgical treatment of peritonitis are left with infection outside the peritoneal cavity and adhesions inside of it. The anatomic peculiarities of the gall bladder, appendix and Fallopian tubes favor the imprisonment of infection, and about one of these organs the surgeon usually finds pathologic conditions, unless it has been mechanically removed. The author's experience leads him to believe that about 40 per cent. of the possessors of infection and adhesions suffer from recurrent attacks of acute and subacute peritonitis, and less than 1 per cent. from mechanical obstruction of the bowels. He believes that the pathology that the remaining 59 per cent. carry within their abdomens is responsible for much distress and many deaths attributed to other causes or to no well-defined cause.

Surgical Treatment of Tubercular Peritonitis.

DR. D. S. FAIRCHILD, Clinton, Iowa, reached these conclusions:

1. If an intra-abdominal focus of tuberculosis is diagnosed or is suspected, an abdominal section should be made with the veiw of a more efficient treatment.
2. If a chronic tuberculosis of the peritoneum with ascites is diagnosed, or believed to exist, a laparotomy is indicated as soon as it is found that medical and hygienic treatment has failed.
3. In fibrous tuberculosis of the peritoneum, the same course should be pursued, and if cheesy degeneration has not commenced, or progressed too far, a certain percentage of recoveries will follow.
4. In acute tuberculous peritonitis, with ascites, and high temperature, laparotomy is useless.
5. In extensive adhesive tuberculosis, with matting of the intestines, laparotomy is useless, and the attempt to separate the adhesions is dangerous in its immediate results.

Injury to Nerves Following Fractures.

DR. A. L. WRIGHT, Carroll, Iowa, reported a fracture of the humerus through the middle third, with injury to the musculospiral nerve between the ends of the bone or by pressure by the callus.

Treatment of Nevi.

DR. JOHN P. LORD, Omaha, discussed the varieties of nevi, their etiology and pathology, and reported several interesting cases. He said the hot water treatment of cavernous angiomas, as suggested by Wyeth, is under trial, and will doubtless have a place in the treatment of selected cases. The treatment of port-wine marks by electrolysis is too tedious and painful for large areas. The results are not perfect, in that they are seldom complete, and leave some scarring. The *x*-ray promises better, and hot air would seem to have possibilities. Electrolysis occupies first place in hairy nevi, and will probably continue to do so unless the *x*-ray will produce permanent atrophy of the hair follicles. The operation of excision of very large tumors will probably never be supplanted by anything less radical; and hitherto inoperable tumors are rapidly yielding to the control of the operators of the new century.

Hypernephroma.

DR. M. L. HARRIS, Chicago, summarized his points thus:

1. The hypernephromata are tumors of adrenal tissue and therefore probably neither sarcomatous nor carcinomatous.
2. Such tumors may or may not form metastases. When they do, they are distinctly malignant.
3. When they are within the kidney capsule, or have perforated it by extension, the kidney should be removed.
4. When they originate in the adrenal proper, they are usually separated from the kidney tissue by a connective tissue capsule, and however much the kidney may be flattened, or fixed, to the tumor, a line of cleavage may usually be found which will allow of the kidney being separated from the tumor and saved to the patient.

In the discussion Drs. C. W. Oviatt, Oshkosh, Wis.; Van Buren Knott and A. C. Bernays, St. Louis, reported cases.

DR. J. E. SUMMERS, JR., Omaha, reported "Two Cases of Acute Intestinal Obstruction Following Contusion of the Abdominal Walls."

DR. HENRY T. BYFORD, Chicago, described "A New Method of Shortening the Round Ligaments Intraperitoneally for Retroversion of the Uterus," which will appear in full in THE JOURNAL.

Dermoid Cysts of the Intestinal Tract.

DR. WILLIAM JEPSON, Sioux City, Iowa, presented a paper on this subject and reported an interesting case. The points of interest which these cysts have for surgeons are: 1. That in a large per cent. of the cases the cysts, although innocent in themselves, ultimately lead to a fatal issue, either through

obstruction of the intestinal lumen, or because of their contents becoming infected from the intestinal canal, terminating in peritonitis. 2. If their removal is undertaken before such complications have resulted, a favorable termination can be looked for.

Appendicitis—Operation and Indications.

DR. A. C. BERNAYS, St. Louis, read a paper with this title. The author laid stress on the fact that we can know nothing definite about the pathologic process which would warrant delay in operating. He believes many lives are lost because the physician is lulled into hopeful security by an amelioration of symptoms which can not be depended on to last; it may change and the favorable time for operation be missed. In so-called intermediate cases a waiting policy is justified because the system is immunizing and fortifying itself against the toxins. An operation after the body has been immunized, which means that the pus has been made less virulent, is less dangerous. Dr. Bernays thinks that an operation is likely to be less dangerous on the seventh or eighth day than on the third or fourth, but pleads strenuously for operation on the first or second day of the attack, and claims that 98 per cent. of all cases operated on at that early period will be saved.

Hyperplasia of the Uterus.

DR. C. G. GEIGER, St. Joseph, Mo., discussed the causes and varieties. The treatment of the various conditions is so dependent on their causation that each case demands a separate investigation. The ideal way of approaching this subject lies in the direction of prevention, which, in a great many cases, the attending physician is able to do. But gynecologists must meet the disease already developed and devise methods which, if not curative, are palliative. Iodin and caustics in the hands of the essayist have not been of much service. He believes that caustics do more harm than good. In neurotic patients nothing is better than a change of climate and scenery. In some cases a change in the surroundings accomplishes much good. To sum up the treatment briefly, the patient should be given rest, the cause removed, the diseased organ depleted and, if possible, the patient's general health improved.

DR. J. N. WARREN, Sioux City, Iowa, contributed a paper entitled "Some Questions in Abdominal Surgery."

AMERICAN ROENTGEN RAY SOCIETY.

Third Annual Meeting, held in Chicago, Dec. 10 and 11, 1902.

The President, Dr. G. P. Girdwood, Montreal, Can., in the Chair.

(Concluded from p. 120.)

Radiotherapy in Pulmonary Tuberculosis.

DR. GORDON C. BURDICK, Chicago, contributed this paper. Much of his work was based on a series of experiments conducted on guinea-pigs inoculated with the tubercle bacillus. He found that when a culture of the bacillus is exposed to the Roentgen ray its development is checked considerably, although it in every case failed to kill the germ. Pigs exposed to the ray lived much longer than pigs not so exposed. When the ray was used in cases of tuberculosis in man a slow but certain improvement took place and eventually a good recovery. Cases of fibroid tuberculosis yielded very slowly. Abdominal tuberculosis requires longer treatment than the pulmonary form. In a few cases a tendency to relapse has been noted. In the cases of mixed infection improvement is delayed and there is a very marked tendency to the sudden development of toxemia. Joint tuberculosis, in which only the bones are involved, offers the best results, but permanent relief can not be obtained until complete ankylosis has occurred, and the author advises that nothing should be done with the *x*-ray until this ankylosis has occurred. He used the ray in a total of 43 cases of tuberculosis in all parts of the body with uniformly good results, except in one case, in which death occurred. This was a case of advanced general tuberculosis, and even here the improvement was at first marked.

He does not believe that this is the method of treatment of tuberculosis that the profession has been looking forward to, but that it is only an extremely useful adjuvant in the treatment. For the purpose of gaining a certain end unquestionably good results have been attained with this treatment, but not an absolute cure.

DISCUSSION.

DR. J. RUDIS-JICINSKY, Cedar Rapids, reported 4 complete cures out of 20 cases. In joint tuberculosis he cautioned against idiosyncrasy. In glandular tuberculosis he said the results were bad, as recurrence followed in each case.

DR. RUSSELL H. BOGGS, Pittsburg, reported decided improvement in 6 cases of pulmonary tuberculosis and an apparent cure after a year in one case.

DR. GIBSON, Birmingham, Ala., also reported good results.

DR. PHILLIPS, Cincinnati, found that he got better results in treating joint tuberculosis when he used a static cataphoresis instrument, using such remedies as formaldehyd and creosote.

X-Ray Treatment in Intra-Abdominal and Other Deeply-Located Malignant Growths.

DR. CLARENCE E. SKINNER, New Haven, Conn., said that the effect of electricity on cancer is due to the specific influence of the *x*-light on the tissues. He reported 38 cases of malignant growths treated with the *x*-ray with a mortality of 34 per cent. In 3 cases there was a complete disappearance of the tumor; continuous reduction in size of the tumor in 15; temporary reduction in size with subsequent increase ultimately, resulting fatally in one; complete apparent arrest in 4; no effect demonstrable on size of growth in 15; complete permanent relief of pain in 16; complete temporary relief in 3; partial in 8; no relief in 4, and none at all in 10. General condition improved in 14; temporarily in 8; apparently not influenced in 9; in 7 the general condition was not noticeably impaired when the patient came for treatment. Gain in weight in 6; no influence apparent in 32. Hemorrhage lessened in 9; not influenced in 2, and no hemorrhage observed in 27. Toxemia of varying degree in 15 cases. Out of 38 cases there were three apparent cures; 17 continuously benefited and are still improving, with prospects of an ultimate cure; 13 temporarily benefited; 2 not benefited, and in 3 treatment was discontinued by the patients regardless of any benefit.

Every one of these cases was inoperable because of advanced disease and offered a hopeless prognosis by any other method of treatment. Three applications of the ray were made weekly, five minutes at a time, taking into consideration the patient, apparatus and the result obtained from the treatment. The *x*-ray should be used only by skilled operators, as they alone are able to appreciate all the conditions which may arise in the course of the treatment. The application of the rays in different parts is fully discussed and also the methods and attention called to possible dangers.

The author arrives at the following conclusions:

1. The pain of deeply-seated cancers is affected by the *x*-light from slight amelioration to entire disappearance.
2. In many cases the *x*-light is capable of exercising an influence on deeply-seated cancers of sufficient intensity to retard the disease and prolong life considerably.
3. In a certain proportion of cases it possesses sufficient power to entirely overcome deeply-seated malignant processes.
4. A small number of deeply-seated malignant processes exhibited absolutely no indication of being susceptible to the *x*-light.
5. Phenomena indicating toxemia not infrequently accompany the treatment of malignant disease by the *x*-ray. This is due to the elaboration or development of toxins dependent on a retrograde metamorphosis of the tissues insusceptible of regeneration. The effect of the *x*-ray light is due to a stimulation of the reparative functions of the tissues dependent on an inflammatory reaction. Its destructive influence is always exhibited on tissues which are low in vitality.

DISCUSSION.

DR. J. P. MARSH, Troy, N. Y., reported a case of uterine carcinoma referred to him for a hysterectomy, on which he used the rays to a favorable termination.

DR. J. RAWSON PENNINGTON, Chicago, described his shield for application of the rays to growths in the rectum. He favors the high tube for this work on deep-seated growths.

DR. J. N. SCOTT, Kansas City, Mo., believes that all patients operated on for malignant growths should be exposed to the *x*-ray as soon after the operation as possible. It hastens the process of healing in addition to giving the patient the benefit of the ray. It will also stop any tendency to hemorrhage.

Diagnosis of Calculi by X-Rays.

DR. RUSSELL H. BOGGS, Pittsburg, Pa., concludes that the *x*-ray is the only means by which calculi can be diagnosed absolutely, especially as calculous conditions are often very obcure, pointing to other conditions. Even minute particles of uric acid can be radiographed. Many gallstones can not be radiographed because of the position of the gall bladder, change in its position and the composition of the stone. For radiographing gallstones a large amperage should be used for a short time only, however. The apparatus must be a suitable one and the preparation of the patient is as essential as in a surgical operation and is the same. The time of exposure need not exceed from two to eight minutes, depending on the size of the patient. The author reported a number of cases and exhibited skiagrams of cases of renal calculi.

DISCUSSION.

DR. J. RUDIS-JICINSKY, Cedar Rapids, Iowa, advised that in skiagraphing for renal calculi a plate large enough to cover not only the kidney, but also the ureters, should be used. The stone may be located in the ureter. The plates should be examined beforehand to ensure their freedom from spots and imperfections. Skiagrams should be made from front and side so that an accidental air bubble in the plate will not be mistaken for a stone.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Ringworm.

The *Indian Med. Record* advises the following procedures in treating ringworm of the scalp: The hair should be clipped closely surrounding the ringworm and all the diseased hairs should be depilated. The parts should then be thoroughly washed with carbolic soap and warm water, followed by an application of the following ointment:

℞. Acidi carbol.
Ung. citrine
Ung. sulphuris, āā 3iss 6

M. Sig.: Apply locally.

This is said to cause no pain. The sulphur in the foregoing prescription should be doubled in cases of children under ten years of age.

Uses of Sulphur.

W. O. Bunnel, in *Med. Council*, recommends sulphur in sexual impotency and for hemorrhoids; in ulceration involving the anal region sulphur ointment dram one (4.00)) to the ounce of adeps (30.00) should be used, applied internally and externally. He also recommends it in incontinence of the urine and chronic catarrh of the bladder. It is useful in anemia, accompanied by amenorrhea, in chronic rheumatism and in scrofulous conditions of the glands or joints. It is of value in the treatment of all skin diseases of parasitic origin such as scabies, etc., applied as follows:

℞. Sulphuris .....ʒi 30
Potassii carb. 3ii 8
Adipis .....ʒv 150

M. Sig.: Anoint the parts two or three times a day after having cleansed them with soap and water.

He recommends sulphur locally in diphtheria, blown or dusted on the membrane. It is of service in the treatment of skin diseases, given in the form of a sulphur bath by allowing the fumes to envelop the body by sprinkling the sulphur on a hot iron after first placing the patient on a cane bottom chair, enveloping him with an awning.

As a hair tonic it is recommended in the following combination:

℞. Lactis sulphuris 3i 4
Olei bergamot .....gtt. x 65
Triturate and add:
Glycerini 3ii 8
Triturate well again and add:
Aquæ rosæ .....ʒx 300

M. Sig.: Apply with a soft sponge once a day. This is said to produce a growth of hair if the follicles are not dead. It is also recommended in all slow healing ulcers, accompanied by an offensive discharge.

Chilblains.

In the treatment of chilblains which have not ulcerated, the *Rev. Méd de Normandie* recommends to those parts where the skin is simply red and tense that compresses saturated in decoction of walnut leaves be applied. The decoction may be made up as follows:

℞. Walnut leaves 3iiss-3iiiss 10-14
Aquæ (boiling) .....Oii 1000

M. Fiat decoctio. Sig.: Apply on compresses to the affected parts.

The compresses should then be covered with oiled silk. Following these moist compresses the following may be applied locally:

℞. Acidi borici .....gr. xv 1
Acidi tannici .....gr. ivss 30
Petrolati 3iiss 10

M. Sig.: Apply locally thoroughly to the affected parts; or the following may be applied as a powder:

℞. Amyli 3iiss 10
Lycopodii 3iiss 10
Acidi tannici .....gr. v 30

M. Fiat pulvis. Sig.: Apply locally. If the hands are involved gloves may be worn to retain the powder.

The following outline of treatment taken from an abstract in *N. Y. Med. Jour.*, is recommended: Bathe the hands night and morning in a decoction of walnut or eucalyptus leaves, or in dilute plumbi subacetas. Then rub them with camphorated alcohol, eau de cologne or aromatic vinegar and dust with the following powder:

℞. Bismuthi salicylatis 3iiss 10
Amyli .....ʒiii 90

M. Sig.: Apply locally; or:

℞. Acidi tannici .....gr. xxx 2
Glycerini
Alcoholis camphoratæ, āā.....ʒiss 45

M. Fiat linimentum. Sig.: Apply locally; or:

℞. Acidi carbol. .....gr. viiss 50
Menthol 3ss 2
Petrolati 3v 20
Lanolini 3iiss 10

M. Fiat unguentum. Sig.: Apply locally; or:

℞. Salol
Xeroform, āā 3iiss 10

M. Sig.: Apply locally.

The following is recommended to be taken internally:

℞. Quininæ sulph. .....gr. xv 1
Ext. ergotæ aqueous .....gr. viiss 50
Pulv. digitalis .....gr. iss 09
Pulv. belladonnæ rad. .....gr. 3/4 45

M. Ft. pilulæ No. xl. Sig.: One pill three times a day for three or four days.

Worms.

M. B. Pollard, in *Med. World*, recommends the following in the treatment of worms:

℞. Olei chenopodii anthel. 3i 4
Ext. spigeliæ flu. et sennæ .....ʒss 15
Santonin .....gr. viii 50
Pulv. acaciæ 3i 4
Syr. rhei arom. q. s. ad.....3i 30

M. Sig.: Shake and take one teaspoonful three times a day one hour before meals, to be followed three hours after taking the last dose by one tablespoonful of castor oil and ten drops of turpentine.

Urticaria.

The *Indian Med. Record* recommends the following outline of treatment of urticaria: If there is reason to suppose that the stomach contains indigestible matter, a mild dose of vinum ipecacuanhæ and castor oil followed by alkalies, and a simple diet for a few days. In the chronic form the diet must be

carefully regulated and all stimulants must be avoided. The chief remedies should consist of laxatives, antacids, vegetable tonics, and warm or tepid baths. In the acute form, olive oil should be applied to the affected parts or the following combination may better answer the purpose:

℞. Zinci oxidi 3i 4
Glycerini .....ʒss 15
Aquæ calcis .....ʒvi 180
M. Sig.: Apply locally to relieve the itching and irritation.

Avoid meat and eat ripe fruit and vegetables, drink milk and alkaline waters.

Salt Pack in Rheumatic Gout.

According to the *Polyclinic* the treatment employed successfully by Hutchinson, in getting rid of the synovial effusion which may accompany rheumatic gout consists in soaking flannels in a saturated solution of sodium chlorid and applying them to the affected joints and covering them with oiled silk and bandages. This method should be repeated every night until the joint becomes normal again.

Herpes Zoster.

The following combination has been recommended in the treatment of herpes zoster:

℞. Morphinæ sulph. .....gr. iv 25
Collodii (flexible) .....ʒi 30
M. Sig.: Paint over the affected areas.

The foregoing, it is said relieves the burning and pain and aids in rapid return to the normal of the tissues thus protected.

Poulticing Gonorrheal Arthritis.

According to the *Med. Press and Circular* poulticing is a much more successful method of dealing with gonorrheal arthritis than is the application of ointments, ice or salicylic acid. In order to obtain the best results the poultices must be applied as hot as possible and require changing frequently day and night. Experience has shown that surgery is seldom needed in order to open and drain the joint if the foregoing simple method is properly carried out.

Dysentery.

J. B. Brandon, in an abstract in *Tropical Medicine*, recommends the following mixture in the treatment of dysentery when there are frequent movements of the bowels accompanied by pain and the presence of blood and mucus.

℞. Acidi sulph. dil. arom. .....ʒss 15
Tinct. opii .....ʒss 15
Sol. magnes. sulph. arom. q. s. ad.....ʒiii 90
M. Sig.: Take a teaspoonful every three hours in water until the blood and mucus have disappeared from the stools.

He recommends also turpentine stupes to the abdomen and a light diet, consisting of rice, soups, and broths given in small quantities, and repeated frequently.

After the blood has disappeared, pepsin and bismuth may be prescribed in small doses.

In cases of frequent evacuations accompanied by tenderness over the abdomen and a rise in temperature the following may be given:

℞. Hydrarg. chloridi mitis.....gr. ii 12
Sodii bicarb. .....gr. ii 12
Salol .....gr. xxiv 1 60
Bismuthi subnit. .....gr. xxxii 2 12
M. Ft. chartula No. i. Sig.: One such powder every three hours until the tongue cleans. This may be alternated with bismuth subnitrate in two dram doses in the form of a mixture, given every three hours.

[In the foregoing prescription, containing salol, we trust the author has been misquoted as to the dose of that preparation. One should never give a single dose of salol containing twenty-four grains, to say nothing of repeating it once in three hours for perhaps several doses.]

Sulphur in Typhoid Fever.

Vorochiesky, in *Amer. Med.*, has employed sulphur in typhoid fever with the idea of ameliorating the ulcerative processes. He administered sulphur in doses of grains 20 (1.30) every two hours, and to children in doses of grains 5 to 8 (.30-.50) every two hours. According to his observations at the end of three days the symptoms were improved; the temperature had dropped, the tongue was more moist, the diarrhea had disappeared and the sleep and appetite improved. An enema given occasionally will overcome the constipation brought on by the use of the sulphur. He is of the opinion that it forms a protective coating, and thus reduces the danger of irritation to the ulcerated and inflamed mucous membranes. It is also a vasomotor constrictor, thus reducing the hyperemia and is a splendid intestinal antiseptic.

Medicolegal.

Liability for Smallpox Started from Pesthouse.—A pesthouse having been located 300 yards from the boundary line of the city, and 250 yards from the house of Mrs. Clayton, whose child contracted smallpox from the pesthouse, the Court of Appeals of Kentucky held, in the City of Henderson vs. Clayton, reported on page 582 of THE JOURNAL of Sept. 1, 1900, that Mrs. Clayton, who took the smallpox from her child, might recover damages therefor on the ground that the purpose of the statute in forbidding the pesthouse being put within one mile of the city boundary was to prevent the communication of contagious diseases to other persons from the pesthouse, and that it was the natural result that the mother should take the disease from the children living in the family with her. This is brought out by the court in the case of the City of Henderson vs. O'Haloran, just decided, in which it says that it is just as natural, and to be as reasonably expected, that other persons who were members of the family, whether temporarily or permanently, would take the disease. In this latter case, Nannie O'Haloran was a guest at Mrs. Clayton's house, and contracted the disease while there. She went there at Mrs. Clayton's invitation, and spent the night, sleeping in the same bed with the child, Mrs. Clayton answering her inquiry as to what ailed the child, who was broken out with some eruption, that she supposed it was chicken-pox. A judgment for $500 damages against the city is affirmed by the court. It says that if she had been cooking for Mrs. Clayton, whether by the day, week or month, and while cooking there had contracted the disease, which had been brought there from the pesthouse, plainly such a result would be no more remote than Mrs. Clayton's contracting the disease; and no sound distinction could be made between a person who lived in the house for 24 hours and one living there longer, if they both took the smallpox while there. The guest was a member of the family as much as the servant would be. And while it was not to be anticipated, perhaps, that a particular person would visit at this house at this time, or would be engaged there as a domestic, or be there for any other reason, still it was to be anticipated that persons would come there for various purposes, and the communication of the disease from the persons living in the house to these persons was a result as naturally to be expected as its communication from one member of the family to another. The purpose of the statute is to require the persons having the contagion of these diseases separated from the rest of the community, so as to prevent the spread of the disease. It was a result naturally to be expected when the statute was violated that the disease would be communicated to the persons living in the neighborhood, and that not only regular members of the family would take it, but also those who might, for any reason, for the time, be living with them. The court therefore concludes that the damages to this guest were not too remote to be recovered for.

Injury to One Already Diseased—Defective Sidewalk—Damages.—In Jordan vs. City of Seattle (Wash.), an action brought to recover for personal injuries alleged to have been sustained by reason of a defective sidewalk, the jury were instructed that if they believed from the evidence that the party suing was injured through the negligence of the city, and that, at the time of the injury, she was suffering from a varicose condition of the veins in the lower part of the left leg, and that such injury aggravated, augmented and accelerated such varicose condition, and the suffering occasioned thereby, then

their verdict would be for the party suing, unless they found that these conditions not only might have arisen, but must have arisen, if the negligence of the city (if they found it negligent in the premises) had not intervened. If the original act of the city was wrongful, and would naturally, according to the ordinary course of events, prove injurious to some other person or persons, and did actually result in injury, through the intervention of other causes which were not wrongful, the rule was that the injury should be referred to the wrongful cause—pass by those which were innocent. If one is reasonably responsible for the act, he is chargeable for direct result of the act, however surprising. The rule is, if by reason of delicate condition of health the consequences of a negligent injury are more serious still, for those consequences the defendant is liable, although they are aggravated by imperfect bodily conditions. The duty of caring and of abstaining from the unlawful injury of another applies to the sick, the weak, the infirm as fully as to the strong and healthy; and when the duty is violated the measure of damages is for the injury done, even though the injury might not have resulted but for the peculiar physical condition of the person injured, or may have been augmented thereby. The proximate cause of an injury is the efficient cause; the one that necessarily sets the other cause in motion. The public streets and sidewalks in a city are not constructed and maintained for the sole use of the healthy and robust people, but for the use of the infirm, the sick and decrepit as well. They may lawfully be traveled by every citizen, without regard for age, sex or physical condition. If the city negligently permits such streets and sidewalks to remain out of repair, and any person, who is free from negligence, is injured, the city is liable for the injury. The city is chargeable with the knowledge that people of different bodily conditions travel its streets, and that among those are the weak, the decrepit and those with organic predisposition to disease. It is reasonable to expect that in certain cases, if an injury happens to one of the latter class, full recovery therefrom may be retarded or prevented by such predisposition or tendency to disease, and the city is chargeable with knowledge that such tendency to disease might greatly aggravate a bodily injury, etc. The Supreme Court of Washington thinks no error was committed by the instructions given, which it thinks are sustained by the great weight of, if not by universal, authority. Furthermore, it refuses to hold a verdict for $6,090 excessive, as it says sufficient testimony went to the jury that the ulcerations formed by reason of the accident were permanent, and that the party suing was partially disabled, and probably would be for life, in addition to which an exhibition of the affected parts was made to the jury, so that they had a better opportunity to determine the malignity and baleful effect of the injury than this court.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Philadelphia Medical Journal.

January 3.

1 *Gastroptosis: A Critical and Clinical Study with Reference to 100 Cases. Albert P. Francine.
2 A Report of a Case of Chronic Splenic Anemia. James E. Talley.
3 *The Perineum. James D. Love.
4 A Local Electric Light Bath. C. C. F. Nieschang.
5 A New Reducing Cyrtometer. Robert P. Elmer.
6 A Case of Traumatic Rupture of the Bladder—Recovery. Edward A. Schumann.

1. **Gastroptosis.**—Francine's lengthy article discusses all divisions of the subject. It refers to a similar article by Drs. Steele and Francine in THE JOURNAL, Nov. 8, 1902, p. 1173, which was based on 70 cases. The present article discusses 100 cases. The etiology, symptoms and diagnosis are discussed at length, and he finds the etiology difficult to explain. He objects to gastric inflation by carbonic acid and to Einhorn's gastrodiaphane and Turck's gyromele. Inflation of air according to Runeberg's suggestion is the method recommended. The indications for treatment are to relieve the stagnation and fermentation and increase the motor power and peristaltic activity of the organ, to furnish support to the stomach and other abdominal viscera, relieving local congestion, to tone up the general health and mental attitude. He gives formulas to combat fermentation in the stomach, and mentions abdominal supports and operation, which last he hesitates to recommend except in extreme cases.

3. **The Perineum.**—Love comments on the evils following perineal injuries and thinks they are usually inadequately treated. Many cases of perineal laceration may be due to faulty position of the mother during childbirth. It is his custom to deliver all primiparæ, at least, in the left lateral prone position, which makes the obstetrician master of the situation. Immediate repair, when possible, is insisted on, but he does not think it necessary to enforce the dorsal position or bind the knees together. He objects to the vaginal douche after operation, both on account of the possible risk to the sutured parts and for the danger of infection.

8 *Tabes Dorsalis: A Study of 140 Cases of Locomotor Ataxia. Joseph Collins.
9 A Case of Supernumerary Breast in the Axilla of an Adult Male. Frederick Griffith.
10 The Diuretic Action of Rectal Irrigation—The Specific Action of Normal Saline Solution in the Production of Diuresis. Robert Coleman Kemp.
11 *Hematocele. W. C. Bowen.
12 *Why Chloroform Should Be Used in Puerperal Eclampsia. Douglas H. Stewart.

7. **Yellow Fever in Cuba.**—Gorgas gives the history of the Havana work, calling attention to the peculiar habitat of yellow fever, the conditions which will stop its spread, and prophylaxis by quarantine. He remarks that Havana since the American occupation has averaged over 17,000 non-immune immigrants every year, a constant source for renewing the disease. In this respect it differs from other localities excepting perhaps Rio Janeiro. He describes the methods used, as narrated in THE JOURNAL, Nov. 15, 1902, page 1274. As a result, while in 1900, the year previous to the beginning of mosquito work, there were 344 deaths in Havana from malarial fever, in 1901 there were 151 deaths, and for the first nine months of 1902 there were only 68 deaths, which would give an average of 90 for the whole year if the ratio were continued, showing that the anopheles, which was especially a suburban mosquito, was pretty thoroughly decimated. He thinks that if the same measures were adopted in Rio Janeiro yellow fever would gradually become a disease of the past.

8. **Tabes Dorsalis.**—This first paper of Collins reviews the history of the disease and its etiology, with special reference to syphilis. He points out the large percentage of cases in which a positive knowledge of syphilis can be ascertained and the difficulties of making the statistics absolutely complete. He says that all we know of the etiology of tabes may be said in a line; it occurs in civilized, mature men and women who have had syphilis and in children who have inherited syphilis. It is a marvel, considering the prevalence of syphilis, how a few are chosen for tabes and the rest spared. The bacteriologist must discover the cause of syphilis, or if it has been discovered, corroborate it, and in co-operating with the physiologic chemist, discover the immediate cause of locomotor ataxia and of general paresis.

11. **Hematocele.**—Bowen describes diagnosis, effects and treatment.

12. **Chloroform.**—Stewart remarks that sugar is an antiseptic, that glycosuria counteracts the tendency to eclampsia by delaying the alkaline decomposition, that chloroform is a producer of temporary glycosuria and brings about a condition which is antagonistic to puerperal eclampsia. Therefore, chloroform is the anesthetic of preference in puerperal convulsions. It will limit the production of the chief poison causing the disease.

21 The Physician and the Pharmacopeia. M. I. Wilbert.

13. **Hip-Joint Dislocation.**—Gibney gives his impression of the Lorenz operation. He was not prepared to see him break down the adductors so quickly and bring the limb into complete abduction. This was accomplished by pulling with one hand and deep pressure on the muscle by the thumb and finger followed by blows with the ulnar border of his hand. The next move was to make extreme flexion of the thigh, the leg being extended; adduction, rotation and pulling until the head of the bone was on a level with the rudimentary acetabulum. A wedge-shaped piece of wood, covered at the top with kid, seemed to be the most important element in the reduction, giving a fulcrum behind the trochanter major, which enabled him to bring the head from its old position forward until it rested under the femoral vessels and could be distinctly felt. Lorenz goes farther than this and forces the abducted thigh back of the plane of the pelvis until he has stretched the capsule so that the slipping back and forth is easily accomplished. The amount of stretching and tolerance of the tissues was remarkably shown, and demonstration of the stability of the bone after reduction was admirable. In placing the thigh in complete outward rotation and abduction a plaster-of-paris application was made extending from the internal condyles to the free ribs, cut out above the genitals and below the stomach, but very thick across the lower part of the abdomen. Lorenz places most stress in the after-treatment on the function of bearing weight. The child is taught to walk, and in this way the head of the femur, more or less imperfectly formed and misshapen, induces a certain amount of irritation and encapsulation. The demonstration was so clear that the following morning Drs. Whitman, Warren and Gibney were enabled to replace eight dislocated hips within an hour and a half. The subsequent treatment is comparatively simple. The different positions must be maintained for months, and Lorenz makes this a strong point.

14. **Lorenz Hip Redresseur.**—Jaeger describes and illustrates this instrument, and states its advantages; also the advantages of the "Lorenz spica," among them its inexpensiveness and absence of inconvenience to the patient.

16.—See abstract in THE JOURNAL, XXXIX, p. 1338.

17. **Abdominal Rigidity.**—The diagnostic significance of abdominal rigidity in cases of peritoneal involvement from various causes are emphasized by Blake, who summarizes as follows:

Abdominal rigidity is a constant symptom in all irritations and inflammations of the peritoneum, and is, therefore, a valuable sign in the diagnosis of the presence of foreign materials in the peritoneal cavity, even before inflammation has ensued. It is a fairly accurate index to the severity and extent of a peritoneal implication, and is, therefore, valuable in observing the course and estimating the severity of a peritonitis. It is a more reliable sign than pain or tenderness in the diagnosis of perforation occurring in typhoid fever. On the other hand, we must remember that the determination of rigidity in the upper part of the abdomen is not always easy, and that it may be present in inflammations of the pleura, the peritoneum being normal.

18. **The Morphin Habit.**—The hyoscin treatment originated by Lott has proved perfectly satisfactory in Goldan's hands. It consists in frequent hypodermic injections of hyoscin hydrobromid, beginning with 1/400 to 1/200 of a grain to determine the idiosyncrasy, and then slowly increasing and repeating it often enough to keep the patient under its influence for two days or more; later the length of time between the doses may be lengthened from one to two or three hours. A nurse must be in constant attendance and attention given to the respiration, heart, and mouth, which becomes dry. The room must be darkened and food given by enemata. The patient should be protected from changes in temperature, as he is liable to perspire profusely. Active delirium is apt to occur, and friends should be kept from the room as far as possible. All his cases have been successful; two are reported in detail.

19. **Bronchial Phthisis.**—Abrams describes this condition as closely resembling pulmonary phthisis when the bronchi are perforated, but the progress is slower. Pulmonary phthisis may coexist. Dulness over the manubrium sterni may extend to the right and left sternal line and often along the course of the bronchi. It is wise, he says, to accentuate dulness by percussion at the end of forced expiration. It is also important to have an assistant press forcibly on the lower end of the sternum. The posterior dulness will correspond to the fourth, fifth and sixth dorsal vertebræ and some distance on either side. Auscultation signs are nearly always present. If the main bronchus is obstructed, the vesicular murmur on the affected side is diminished or abolished, and the same is true as regards vocal fremitus and respiratory excursions. More often whistling sounds are heard during inspiration and expiration. A subjective feeling of weight in the upper chest region and spasmodic cough are observed in all these cases. Swelling of the cervical veins, edema and cyanosis of the face or arms, etc., may be present. The Roentgen ray signs are characteristic, showing enlarged bronchial glands and the lung negative. The diagnosis is not difficult, though syphilis may give some trouble. The course of the disease is long unless pulmonary phthisis coexists. In only one of his cases was a positive cure effected. Four patients are under observation who have had symptoms of cough and expectoration for more than ten years without any material involvement of their physical well being. Most dated their disease to some acute infection, notably measles and pertussis. The treatment is much the same as that of pulmonary tuberculosis. Residence at the seaside should be tried. Syrup of iodid of iron seems to have some effect. Potassium iodid was employed in the only case in which a cure was effected; the patient gave a history of syphilis. He has lately been employing inunctions of sapo viridis, one dram, rubbed in daily in different portions of the body, usually with good results. He has picked this point up somewhere in the literature, but can not give the reference.

20. **Pulmonary Tuberculosis.**—Wark insists on the general measures of treatment, improvement in respiration and circulation by proper exercise, change of climate, improvement of nutrition, especially when there is defective assimilation of fats. He mentions two drugs which he thinks will restore the ability to develop the fatty materials from the carbohydrates and other food elements. These are *Verbascum thapsus* and *Sticta pulmonaria*. Of the former he can not speak too highly as a weight increaser in this disease.

26 The Close Analogy of Trachoma to Adenoids. Ralph Opdyke.

22. **How to Study Anatomy.**—Smith lays down a plan of teaching anatomy according to the developmental method, studying the several systems and tissues theoretically and systematically, instead of learning the subject by rote as at present.

23. **Headache.**—The various forms of headache are noticed by Leszynsky as the result of a clinical study of over 5,000 cases during the last twenty years. In a large majority headache is due to toxemia either from constipation or intestinal or gastric indigestion. In these cases it is usually frontal, but may be general. Gastric indigestion may produce it reflexly through the pneumogastric nerve, and headache due to both gastric and intestinal causes is frequently an accompaniment of stomach dilatation. Headache due to renal disease may be either uremic or congestive. The importance of urinary examination for uremic headache is specially remarked on. There are two kinds of rheumatic headache, one due to suboxidation and autotoxemia, and the other a muscular rheumatism or myositis of the scalp. The latter may be induced by exposure to cold like other forms of muscular rheumatism. Gouty patients are specially subject to headache as

are also diabetics, and in them it is often accompanied by hebetude and depression of spirits. Headache is a common symptom of nearly all the infectious diseases and fever; is often due to the toxic action of alcohol, coffee, lead, etc., and it is an important symptom of neurasthenia, though not always present. Its importance in epilepsy is at times very great, especially in diagnosis of obscure cases. He considers a constant general headache with optic neuritis and frequent attacks of vomiting, invariable signs of intracranial disease. [This is a rather general statement which should be considered open to exceptions.] Syphilitic headache is a matter of importance. He insists on the necessity of careful examination of the entire organism in every case to clear up the cause. The treatment is briefly noticed.

25. **Cold and Disease.**—The action of cold and draughts in producing disease is explained by Tuthill as due to the arrest of secretion from the mucous glands, allowing the pathogenic bacteria present at the time to become active. Ordinarily they are restrained by the normal secretions. This is the philosophy of taking cold, according to his views.

28 *Percentage Modification of Milk in Infant Feeding. Maynard Ladd.
29 Foot-and-Mouth Disease. Langdon Frothingham.
30 *Chlorid of Ethyl as a General Anesthetic. Charles G. Cumston.

27. **Primary Multiple Tumors.**—Woolley argues for the existence of a systematic neoplastic tendency, which may produce multiple primary malignant tumors otherwise than by metastases. He begs observers to watch for cases of multiple primary growths and record them, with careful statistics of the general conditions, as well as the special ones surrounding the patient.

28. **Infant Feeding.**—Ladd gives formulas and tables and explains them in detail.

30. **Chlorid of Ethyl.**—Cumston gives the history of chlorid of ethyl narcosis and its methods of administration, and claims for it that it is safe so that an experienced anesthetist is not required. It can be given by any careful physician, thus having special advantages for operations of short duration. When used as a preliminary to ether, it avoids the period of excitement and on account of its pleasant odor and non-stifling effect, the most nervous patient can take it. The amount of ether afterward used may also be much reduced. Transition from one anesthetic to another is quite insensible. Thus far no contraindications have been pointed out, though they may yet be discovered. He finds kelene and antidolorin very pure and reliable, and he has recently tried anodynone and found it also satisfactory. He concludes with brief reports of over forty cases. He has used the drug in 153 cases without the slightest accident and with much comfort to the operator and patient.

31. **Cardiorespiratory Phenomena Revealed by the X-Ray.**—Abrams describes the cardiac changes and movements as revealed by the *x*-rays, showing the position of the heart, as varied by attitude and respiration, aneurism, position of the diaphragm, dislocation of accommodation in aortic aneurism, old age, etc., the relation of the stomach and the colon to its position, the effects of coughing and laughter, amyl nitrite, rarefied and compressed air, etc. He does not think an *x*-ray study of heart pulsations supersedes the conventional physical signs unless it is in the diagnosis between enlarged heart and pericardial effusion. In the former the pulsation may be discerned, but not in the latter. He does not like to diagnose aneurism with no other aid than the rays. He points out that paroxysmal laughter causes the heart to bob up and down, and might be dangerous in cardiac disease, by inhibiting the return of the venous circulation and dislodging thrombi. The heart reflex consists in myocardial contraction from cardiac irritation in the precardial region. He finds that this can not be elicited when the cardiac muscle is beyond restitution in myocarditis, and it can be noted not only in transverse but in the sagittal diameter, and will often aid in excluding the murmurs of relative insufficiency. Here vigorous rubbing of the pericardium will temporarily dispel the latter murmurs. It can also be elicited from the nose, and he suggests the expediency of cocainization of the nasal mucosa before using an anesthetic, on account of possible affections of the heart. Many cases of death during anesthesia may be caused by undue stretching of the neck during chloroform or ether anesthesia. The lung reflex of Cherchevsky has been investigated by Abrams, who does not find it important in the diagnosis of arteriosclerosis. The lung reflexes of contraction and dilatation will be discussed in a future paper. He thinks they can be explained only by supposing two distinct functions of the vagus, one enabling it to dilate and one to contract the bronchioles.

44 The Treatment of Respiratory Diseases, with Especial Reference to the Employment of Terp-heroin. C. H. Powell.

41. **Burns and Scalds.**—A few points mentioned by Piquard in injuries from railroad accidents are: 1. The frequency of serious complications; 2, the need of thorough sterilization of the parts after removing the first of the temporary dressings. He uses a mild carbolic solution here for its anesthetic qualities. Moist dressings of saturated solution of picric acid are very useful in suppurating cases. In bad scalds of the hand it is very essential that the hand be straightened and placed in that position on a flat splint and kept there until well, otherwise the strong flexors will so contract the fingers as to make the hand useless. The same must be remembered as regards burns or scalds of the popliteal space, the elbow and the wrists, where mechanical appliances must also be used to prevent deformity.

50 *The Accidents of Anesthesia; Their Prevention and Treatment. Daniel N. Eisendrath.
51 Professor Lorenz's Bloodless Reduction of Congenital Dislocation of the Hip-Joint. Edmund Andrews.

45. **Senile Pneumonia.**—Reid remarks that the characteristic features of the disease may be entirely changed in elderly persons. The disease is insidious from the beginning. The symptoms may all be mild and yet the condition prove fatal. Pyrexia is never excessive; cough may be slight, and respiration not difficult in some cases. The crisis may not be well marked. Expectoration may also be absent. When an old person has a slight rigor followed by a rise of temperature, attended by great prostration, for which there is no explanation,

pneumonia may be suspected, though all the symptoms are absent. Reid thinks the increased mortality from pneumonia may be largely due to the diagnosis of senile pneumonia, which was formerly overlooked. He thinks that most of the fatal cases of influenza are complicated by pneumonia. After 40 each decade has a death rate of its own; after 60 the outlook is always unfavorable. In diagnosis we should look to the lungs; but in prognosis the heart is everything. As regards treatment, he advises caution in the use of digitalis, if it is used at all. Alcohol, if it is ever of service, should be in senile cases. Carbonate of ammonia has failed to hold its own in recent practice. Creosote has its advocates, but many doubt its effects. Strychnin has more friends and fewer enemies than any other drug in the pharmacopeia for these cases. Rest, quiet, ventilation, uniform temperature, easily-digested liquid food and intelligent conservative treatment of the symptoms will suffice for a cure in the great majority of uncomplicated cases under 50 years of age. Beyond this limit the mortality will be doubled and quadrupled. In his opinion heroic treatment has no place in the disease and the conservative course will save more lives than the opposite.

46. **Pathology of the Kidney in Croupous Pneumonia.**—Franing describes the conditions in the kidney, remarking especially on the congestive signs, granular degeneration of the epithelioma, fatty degeneration, edemas, etc. He says congestion is more or less marked in 70 per cent., and edema in practically all the congested cases; granular degeneration more or less marked in all and hyaline material in 60 per cent.; swollen tufts in practically all cases; infiltration of lymphocytes and plasma cells in 89 per cent., and of polymorphonuclear leucocytes in 25 per cent.; bacteria in a great majority of cases; hyaline casts in 80 per cent. and granular in a few, Pneumonia, he thinks, can no longer be considered a local infection of the lungs, but frequently a general bacteriemia.

47.—This article appeared in THE JOURNAL, xxxix, p. 1.

48. **Colpeurynter.**—De Lee gives the uses of the colpeurynter in obstetric practice and a historical sketch of the instrument. Its value is noted in induction of premature labor, hastening delivery or preparing for rapid delivery after symphysiotomy or version; in stenosis or rigidity of the cervix or weak pains; in cases of dry labor; in shoulder presentation as a substitute for the bag of waters which has ruptured; in prolapse of the cord; in lifting up the pregnant uterus for hyperemesis, or to replace a retroflexed incarcerated uterus; and especially in placenta previa, particularly in cases where the os is not fully dilated. He urges a wider employment of the rapid, simple procedure.

49. **Transverse Arrest of the Head.**—Reed concludes his article with the following summary:

Deep transverse arrest of the head is a relatively common complication in labor. The diagnosis is easily made from the position of the sagittal suture and the fontanelles. The normal termination of the case can not be awaited in most instances, but forceps should be applied as soon as it is evident that rotation will not occur spontaneously. The blades should be applied in that pelvic oblique diameter toward which the occiput lies. Location of the occiput must be determined before the blades are applied. Traction and rotation must be simultaneous.

60 Case of Abscess of Brain. D. Percy Hickling.

52. **Personality in Medical Education.**—Balloch urges that the personal influence of the teacher should be impressed on the student. He thinks that in the future the great medical school of the country ought to be located in Washington, where the research, laboratory and other advantages are so great.

53. **Flat Foot.**—Shands points out the difference between flat foot and weak foot. Congenital flat feet are not here discussed. The static variety, he says, is most commonly seen in young persons at the time of approaching puberty, with weak muscular development and occupations requiring great strain on the muscles or ligaments that support the arch of the foot. Rapid growth favors it. Injuries of the ankle, ordinary strains, are often the cause of the condition and impairment of the strength of the ligaments and muscles, especially those that support the arch and those of the calf or tibials, the peroneous longus on the outer side in particular. Long standing causes them to tire, and in time to give way, thus flattening the arch. Ill-fitting shoes and acute rheumatism of the muscles are frequent causes, also osteitis, phlegmons about the sole of the foot and contracted tendo Achillis. The diagnosis of flat foot is easily made, but weak foot is not so easy. It is the primary stage of flat foot, and if recognized early and properly treated, flat foot will be avoided. He says a line let fall from the center of the knee cap should fall normally just to the outer side of the second toe, and any deviation from this is apt to indicate a weak condition of the supporting structures of the plantar arch. Eversion of the foot is the most common position of weak foot. Pigeon toe is often due to it also, and can be cured by support. The prophylactic treatment of flat foot should be begun as soon as the weakness is discovered, and he insists on the value of strapping the foot, especially in cases of sprained ankle, preventing serous infiltration and giving support until nature replaces the fibers of the tendons and ligaments. The treatment of flat foot is simple, but the ordinary shoe never properly conforms to the condition. The principal thing is to have the sole of the shoe slightly raised on the inner side. In the mild form of weak and painful foot about all that is necessary is to apply the adhesive plaster strips and then support the arch with a soft pad, fitted so as to conform to the arch as nearly as possible. He applies a pad over the adhesive plaster, holding it in place with two strips of the plaster, and over all applies a snug roller bandage. This is changed once a week, increasing the thickness of the pad each time until the arch is somewhat exaggerated and the painful symptoms have subsided. Then the treatment is continued by leaving off the adhesive plaster and applying a soft pad attached to an inner sole, being careful that the pad is high enough to support the arch in its normal position. In the severer cases, the Whitman flat-foot plate will be of use. In conclusion he insists on prophylaxis as the most important thing.

56 and 57. **Pancreatitis.**—The papers by Hardin and Stone are of interest as summaries of the subject and reports of cases, but contain nothing especially new.

61 *The Gastrointestinal Type of Arteriosclerosis. Walter L. Bierring.
62 Pathology and Symptoms of Appendicitis. A. Siewert Weber.

61. **Gastrointestinal Arteriosclerosis.**—Bierring reports a case and discusses the condition. His conclusions are:

1. That arteriosclerosis produces definite and characteristic changes in the digestive organs, associated with well-marked clinical manifestations, so as to warrant the distinction of a gastrointestinal type. 2. On account of the fact that clinical symptoms closely resemble at one time gastric carcinoma, again intestinal obstruction and chronic diabetes, makes its recognition a matter of importance, especially on account of the influence that a diagnostic error may have on the treatment and in the lowering of the standard of family record transmitted to progeny. 3. Considering the pathologic anatomic changes peculiar to the gastrointestinal type and its possible sequelæ, the more general treatment suggests rest in bed, outdoor life and moderate exercise, indicated in other forms of arteriosclerosis as appropriate.

Merck's Archives, New York.

December, 1902.

63 *A Monograph on the Use of Cinnamic Acid and Sodium Cinnamate in the Treatment of Tuberculosis. (Continued.) William J. Robinson.
64 *Home Treatment for the Morphin Habit. H. A. Moody.

63. **Cinnamic Acid.**—In the conclusion of his article on the cinnamic acid treatment of tuberculosis, Robinson says that to regard the drug as a specific is ridiculous, and it is not so claimed by Landerer or Cantrowitz, his most ardent follower, but it is probably a useful adjunct in the treatment of the first stage of tuberculosis. The doses must be small to begin with and be very gradually increased. Landerer insists on this

point. It is contraindicated in cases inclined to hemorrhage, and soon after hemorrhage, and when the temperature is above 101 F. Should a rise of temperature follow its injection the dose is too large, and the next dose should be diminished one fourth or a half. There is no justification for mistrusting Landerer's statements, but it must be remembered that similar results are obtained without the use of this drug. The treatment is harmless if directions are followed. Too large doses may cause excessive serous exudation around the tubercle foci and carry some bacilli into the circulation. Given by the mouth the doses of sodium cinnamate may be large, but it remains to be shown whether, thus administered, it has any effect on the tuberculous processes. Taken altogether, Robinson's impression of sodium cinnamate as a curative agent in tuberculosis is a negative one. It is probably a useful stimulant, but he prefers creosote or some of its derivatives.

64. **The Morphin Habit.**—Moody's home treatment is mainly use of the bromids, with hyoscin and spartein as adjuvants.

65 *Recent Studies of Immunity, with Special Reference to Their Bearing on Pathology. William H. Welch.
66 *The Importance of a More Radical Operation in Carcinoma Cervicis Uteri as Suggested by Pathological Findings in the Parametrium. John A. Sampson.
67 *Nitrogen Excretion in Pneumonia, and Its Relation to Resolution. Henry W. Cook.

65.—See editorial in THE JOURNAL, xxxix, p. 1116.

66. **Carcinoma of the Cervix.**—Sampson insists on a more radical operation in these cases, and gives the details. The operation is similar to that of Wertheim. The lymphatics along the pelvic vessels, and also the parametrium, should be removed en masse with the uterus, because an enlarged gland is not necessarily an invaded gland, and cancer may be present in very small lymph nodes, making it impossible to always diagnosticate cancerous lymphatics. If the ureter should be adherent to the parametrium, the lower portion of it should be sacrificed and all the tissue from the cervix to the pelvic wall removed. If the ureter is dissected free, two things are very apt to occur: The disease will probably return and a ureterovaginal fistula will probably occur from injury to the blood supply of the ureter. The lymphatics should be removed from the pelvic vessels from above downward, together with the uterus and all the tissues lateral to the cervix from pelvic wall to pelvic wall undisturbed, including the lower 4 cm. of the ureters; and the ureters should be implanted in the bladder.

67. **Pneumonia.**—Nitrogen excretion in pneumonia is specially discussed by Cook, who sums up as follows:

1. In cases of pneumonia a surplus amount of nitrogen must be excreted during the days of resolution that will correspond at the least to the original quantity of exudate poured into the involved lung. In most cases there is more, the rest representing in great part a continuation of the formation and an absorption of inflammatory exudation, plus other tissue destruction.
2. In cases of marked delay in resolution the continued high nitrogen output indicates a continuation of the local inflammatory process, so that in those cases of several months' persistence we might speak of a chronic pneumonia.
3. In cases of rapid resolution the leucocytosis curve follows the curve of nitrogen excretion with a very striking parallelism, and would seem to point to a causal relation between leucocytes and resolution.

69 Report of a Case of Bubonic Plague. E. L. Wemple.
70 *Points in the Management of Cleft Palate Cases, Before, During and After Operation. Harry M. Sherman.
71 Suturing of Muscles and Tendons. D. D. Crowley.

68. **Standardization of Drugs.**—Stewart illustrates the importance of the subject and recalls a former article published in THE JOURNAL of April 27, 1901, on a proposed national bureau of materia medica, giving the objects of such a bureau and its utility.

70. **Cleft Palate Cases.**—Sherman notes certain special points: the necessity of proper preparation of the patient, accustoming the child to the use of the spray, removal of adenoids, care of defective teeth, and in every way securing a clean mouth before operation. Chloroform is the anesthetic which he prefers, and he uses the position of Rose, holding the child's head on a towel pinned across the operator's knees, so that it can be rolled in either direction by raising one knee or the other, while the larynx and throat are easily kept free from blood. He illustrates the instruments. The operation he generally uses is the uranostaphylorrhaphy of Trelat. Occasionally he has followed the method of Ferguson of Chicago. He has used in the nose Dobell's solution, to which the child, who has been trained, submits with little resistance. He has used where this was not applicable in the mouth a 1 per cent. chloral solution, and for staphylococcic infection a 2 per cent. salicylic acid solution in alcohol. The child should be fed by the rectum. He had 13 patients and 26 operations. All the successes were by uranostaphylorrhaphy.

72 Factors in the Ordinary Treatment of Eye Diseases. James C. Hancock.
73 *Some Peculiarities of Pelvic Pain. John Cowell MacEvitt.
74 *Points of Similarity and Difference in the Onset of Typhoid Fever and Appendicitis. William F. Campbell.
75 A Case of Multiple Ulcers of the Stomach in a Child; Sudden Death. C. F. Barber.
76 Report of Epileptiform Attacks Cured by Nasal Operation. Stephen H. Lutz.

73. **Pelvic Pain.**—The pain attending menstruation is especially noted by MacEvitt, who thinks that we can distinguish between ovarian and uterine pain by the constant and dull character of the former and the more intense and intermittent nature of the latter. The most puzzling thing about it is the inconstancy of the pain in relation to pathologic conditions. He has invariably met with the fact that the pain exists in inverse ratio to the size of the tumor cyst and the cystic degeneration of the ovary, the larger tumors often being comparatively painless even in their incipiency. He reports cases and considers that the sympathetic plays a more important rôle in the production of these pains than the cerebrospinal. The causes are, he holds, increased cell production, destructive processes affecting the nerves and the functional disturbances of sensibility, all three acting according to the condition.

74. **Typhoid and Appendicitis.**—Campbell points out the differences between typhoid and appendicitis, the prodromata and often apparently sudden onset of the former. The dry glazed tongue, stationary elevated temperature, comparatively slow pulse, general tenderness of a particular region, and general rigidity, if it exists, with the absence of leucocytosis, indicate typhoid. All these symptoms are the reverse in appendicitis. The only thing which seems to be common to the two is pain in the right iliac region, but this is limited to a special point in appendicitis, while it is more general in typhoid.

81 *The Treatment of Football Injuries Based on an Experience of Six Years. J. B. Carnett.

77. **Typhoid Fever.**—Hare is conservative in his treatment of typhoid, discouraging too active medication, yet he says the skilful use of drugs is not more needed in any other disease. To keep up the action of the kidneys he would give pure water in small quantities. There has been too little attention paid to the function of these organs in this disease. He is skeptical as regards intestinal antisepsis. The drugs used for this purpose are nearly all more or less directly eliminated by the kidneys. Possibly acetozone may prove to be an efficient intestinal antiseptic. He is also not enthusiastic as regards the cold bath, and especially deprecates the simultaneous use of the antipyretic coal-tar products. He finds the cold rubbing even more effective, though it requires more skill on the part of the assistant, and he speaks well of the use of the warm bath (85-90 F.) as a temperature reducing agent in this condition. It does not slow the heart or alarm the patient. Turpentine is an occasional remedy in advanced cases when the tongue is dry and the belly tympanitic. He thinks that in fear of heart failure we often stimulate too early. Aside from the favorable effect of the bath, he thinks most practitioners believe alcohol

is the stimulant par excellence in this condition, and that cold applied over the precordium is valuable in slowing a too rapid pulse. He is doubtful as to the value of digitalis, excepting in unusual cases. Strychnin is often overdone. For diet the patient does not need milk alone, but easily digested starchy foods, or foods of this type, helped in the digestive process by takadiastase or pancreatin. He also allows one or two soft-boiled eggs. With such a diet he thinks the patient is better able to resist typhoid infection. Medical treatment for hemorrhage is not effective. He does not see why a bleeding vessel in the intestine should be regarded differently from a bleeding vessel in the leg, and it is hard to see how remedies given internally can reach the spot. Saline infusions may be employed with advantages within certain limitations.

78. **Gallstones.**—Richardson advocates the use of glycocholate of soda as a solvent for gallstone, besides being the only real cholagogue we possess, purging the liver and assisting in the assimilation of fats from the intestine.

79. **Rheumatoid Arthritis.**—Clemens offers the following treatment as effective in rheumatoid arthritis: The use of syrup of iodid of iron in dram doses three times a day, which will remove the disease in two or three months. Iodism may occur, necessitating diminishing or withholding the medicine for a time. A generous diet should be an adjunct to the treatment.

81. **Football Injuries.**—Carnett describes the various injuries to which football players are liable and which he thinks are usually not serious. The fatalities that occur in football usually take place in smaller colleges and with men who are novices at the sport and physically unfit. The preliminary practice, with hygiene, regulated habits, proper diet, etc., hardens the players so that the injuries which may be serious to others are comparatively slight with them, and the use of proper apparatus for guards minimizes the danger of some of them. He reviews the more formidable injuries and their treatment. Many of them may be painful and yet not absolutely disabling.

1. **Bovine and Human Tuberculosis.**—This address at the Congress of Tuberculosis in Berlin was reviewed in the original. See THE JOURNAL, Dec. 20, 1902, page 1625, title 48.

2. **Malaria.**—MacGregor reviews the subject and the methods of combating it with special reference to the experience at Lagos. He shows Koch's preventive method of using quinin to be of real utility and says objections to it largely rest on misapprehension. The superstition, as he calls it, that quinin, even perhaps in moderate doses, produces black water fever, he says, dies hard. Mechanical prophylaxis by screens and drainage and otherwise destruction of breeding places are treated at some length. He believes that much can thus be accomplished and he does not see the utility or necessity of Europeans isolating themselves from the natives. At Lagos they attacked malaria at all points, by Koch's method and by defensive and offensive measures. He believes that considerable amelioration of the disease in this excessively malaria infected region has been attained.

4. **Bacillus Pestis.**—In this preliminary communication Row gives the results of experiments with the serum of convalescents from plague and finds that it has a remarkable bactericidal efficiency against *Bacillus pestis*. This has been observed in convalescents of over six weeks and has been maintained, though to a less extent, in two patients who had had the plague twelve to eighteen months previously. The serum of patients in the very early stage of the disease is certainly inhibitory to the growth of *Bacillus pestis* while that from normal individuals gives very good growths, though varying in different individuals, but not one instance has been found where the blood had completely destroyed the growth. The value of the serum reaction, therefore, is of scientific interest, but Row thinks it is of doubtful value from a diagnostic point of view, since the observation takes at least twenty-four hours to give a pronounced opinion and the clinical features of the disease develop with such rapidity as to allow no question as to its nature. Yet in a suspected or convalescent new arrival, a positive reaction—that is absence of *Bacillus pestis* in drop cultures—would be of value in giving definite information on which to take preventive measures. He is still studying the reaction in Haffkinized subjects at the various stages before and after inoculation, but his results are not yet ready for publication.

6. **Tuberculous Meningitis.**—Sinclair reports a case characterized by the appearance of transient early aphasia and dysphasia and reports two others from the literature. In each case the trouble was in the initial stages of the meningitis, though secondary to tuberculous disease existing elsewhere, and he suggests that the occurrence of aphasia even of transitory character in a person already suffering from any form of tuberculous disease should be looked on with grave suspicion.

8. **Growth of Bacteria in the Intestine.**—Smith and Tennant report experiments on dogs and rabbits in which they made direct observations of the number of bacteria in the contents of the intestine at short intervals in its course using careful aseptic precautions, opening the intestine with a sterilized knife. They also had an opportunity of studying an example of the human intestine in conditions favorable for the purpose of research in a case of accidental death a few hours before the examination. The results of investigation and their bearing on the pathology of a number of diseases are discussed. They show that the small intestine through most of its course is comparatively sterile while the focus of bacterial disturbance is in the region of the ileocecal junction. The power of inhibiting bacterial growth having become impaired, the bacteria which occur naturally in the large intestine become more abundant and approximately similar changes occur in the small intestine. These occur to a greater extent near the ileocecal valve than in the higher portions of the small intestine and this is just the region which is liable to be subject to attacks of inflammation, as in appendicitis, typhlitis, typhoid fever, and intestinal tuberculosis, etc. Pathogenic bacteria taken by the mouth will be restrained from multiplying until the lower ileum has been reached. In the human subject exactly the same condition was found as in animals.

9. **Obscure Abdominal Pain.**—Bennett reports two cases, both puzzling as to the diagnosis, in which operation revealed no adequate cause for the symptoms. In one there was before operation no doubt as to there being obstructive jaundice, either simple or complicated, and yet operation showed that there was nothing to support such a diagnosis in either the liver, gall bladder or gall duct. It is a curious fact, too, that anodynes of the nature of phenacetin had more complete control over the pain than morphin injections, and it is noticeable also that after the urine and feces had become perfectly normal, the main features of the case showed very little alteration. The subsidence of symptoms after operation suggested functional nervous disturbance, but it is hard to see how this could account for all the symptoms of illness and of high temperature lasting nearly four months. In the second case diverse diagnoses were made, including gastric catarrh, duodenal ulcer, gallstones, gastroptosis, cancer, etc. There was found a perfectly normal gastric mucous membrane and a normal pylorus with no signs of chronic catarrh and no scars of ulcers, though old fibrous adhesions were found. He suggests a possible edematous condition of the duodenum or pylorus with disturbed innervation and neuralgic pain might account for the fibrous hyperplasia that was found. In a note to the article Sir William Bennett suggests that complete relief, which at the time of the writing was not apparent, will ensue later, as the result of treatment, and Pritchard, in a later note, says that this prediction has been partially realized.

10. **Hernia.**—Renton calls attention to Roux's radical method, the peculiar feature of which is the holding down of Poupart's ligament by a metal staple passed obliquely through it over the crural canal and into the pubic bone. It must be driven in securely but not tight enough to injure the ligament, and gives no trouble, remaining *in situ* in over 60 cases operated on by Roux. Renton has found the method very satisfactory.

12. **Poliomyelitis.**—Several cases are reported by Batten illustrating the different forms of superior and inferior polioencephalitis and poliomyelitis. He discusses the pathology and considers that there are decided evidences in favor of its being directly due to primary vascular thrombosis and that its direct bacterial origin is supported by the fact of its prevalence during certain periods of the year and its occurrence in epidemics. His arguments are drawn chiefly from pathologic examination of the spinal cord, but he thinks they apply equally to the cerebral cases.

13. **Congenital Hypertrophic Stenosis of the Pylorus.**—Cautley and Dent have seen a number of cases, two of which are detailed; they discuss the operative treatment. They see

decided objections to pylorectomy, considering that it is too severe an operation. Gastroenterostomy has been employed in nine cases, with four recoveries. Their objections to this operation are stated as follows: That it necessitates considerable exposure of the abdominal contents, must necessarily be protracted and that there is increased risk of protrusion of the intestine, and the incision has to be extensive. Anterior gastroenterostomy has been adopted in all cases; posterior gastroenterostomy, the better operation of the two, is still less practicable in children. Dilation of the pylorus, some form of Loreta's operation, has been performed in six cases with four recoveries. Pyloroplasty was performed in the two cases reported, and in another recent case. It would appear that the balance of opinion is decidedly in favor of gastroenterostomy, that pyloroplasty is not so much an unsuitable as an impracticable operation, but this is contradicted by their experience. The operation is really much easier when fixation is due to muscular hypertrophy as in congenital pyloric stenosis, and they describe their technic. They think in these cases it is preferable to dilation because it can be done at least as quickly, it is a more definite proceeding and allows more range. The lumen of the tube can be examined, and if desirable the longitudinal fold of mucous membrane can be removed. The exact amount of injury to the parts is known. There is no advantage, they think, in performing what is called "submucous pyloroplasty," and it is better to divide all the coats. The etiology of the condition is considered, on the whole, not very clear. The balance of evidence is in favor of the hyperplasia being primary.

14. **Diphtheria.**—Cairns parallels plague and diphtheria in their reaction to serum treatment and sees a striking analogy. There is the same local action at first, followed by a tendency to dissemination of the organism. Special involvement of the lungs is particularly noted and the advantages of intravenous injections of antitoxin pointed out. In 20 out of 50 consecutive cases this method was followed, and in a fairly severe type of the disease, 31 of the 50 being laryngeal cases, 15 of them complicated by bronchial pneumonia of more or less severity. In 17 tracheotomy was performed. The mortality was 6 per cent. as compared with 10.7 per cent. in the previous year, in spite of the greater severity of the cases. The three deaths were respectively due to malignant diphtheria, to paralysis complicated by chorea in the sixth week of illness, and to double bronchopneumonia in a marasmic child aged 2. The high rate of recoveries is, he thinks, to be attributed to the intravenous injections, and the dose employed varied from 20,000 to 35,000 units. The largest amount injected was 82,000 units in three separate doses, and in spite of the large quantities no untoward results beyond the usual serum rash and pyrexia were observed. The method was first employed in only apparently hopeless cases and later in cases which, though very severe, promised some chance of recovery. It has not yet been employed in the milder cases of the disease. The general indications for its use were considered to be the following: 1. Malignancy, with hemorrhage from the nose or into the skin by glandular enlargement, and by extreme blanching of the skin; 2, any marked involvement of the lungs, either on admission or subsequently; 3, a moribund condition on admission; 4, a profoundly toxic condition of the patient. In such cases an initial dose of 20,000 to 25,000 units is perhaps not excessive. If the patient fails to respond the dose can be safely repeated. While the number of cases was small they were strictly consecutive and not selected cases.

15. **Smallpox.**—Fraser gives some statistics of the recent epidemic in Southwest Essex, dividing the cases into those which had been once vaccinated, and those which had not been vaccinated at all. Of the former there were 271 cases, of the latter 857. The proportion of mild cases was 36 per cent. vaccinated and 8 per cent. unvaccinated; the discrete were alike 45 per cent. in each, while the confluent cases were 19 in the vaccinated and 47 in the unvaccinated. This shows the protective power of even a single vaccination in infancy as regards the incidence and severity of the disease.

18. **Typhoid in the Army.**—Canney reviews the experience in typhoid fever during military operations, in the recent British and United States wars, and considers that the aerial connection and that by flies must be considered as only of secondary importance to the water conveyance of the disorder. He gives a plan of water supply for armies involving a special water force to see that boiled water alone is used and also for the training of sanitary officers and the medical corps of the army in sanitation.

19. **Reflexes in Rheumatoid Arthritis.**—Jones shows that the increase of deep reflexes is not uniform, while the superficial ones show a marked variability. He has studied them especially in asymetrical cases, and discusses their bearing on the pathology. He thinks the evidence in favor of the infective theory is strong, still proof of spinal change is wanting. He does not, however, believe that specificity can be claimed for any one particular microbe. Given any source of auto-intoxication the resulting toxemia may, through its action in the cord segments, produce what is called rheumatic arthritis, nor does he consider the disease confined to the anterior segments, as does Bannatyne. There is an undue tendency, he says, to centralize all the disease in the joints, to the unfair exclusion of the muscular and sensory symptoms. Increased myotatic irritability is not the only symptom pointing to affection of the muscular system and the changes in the muscular and sensory realms at an early stage of the disorder merit more careful attention.

35. **Gelose Diagnosis of Typhoid Fever Stools.**—Chantemesse announces that by means of his gelose diagnosis he was able to differentiate typhoid fever in eighteen to twenty-four hours, and in some cases even before the disease had progressed sufficiently to allow serum diagnosis. He also states that this gelose method revealed the presence of typhoid germs in the stools for more than a month after the patients had completely recovered. He thinks that the early diagnosis possible by this method justifies the establishment of central headquarters for it, similar to those for the diagnosis of diphtheria, with a view to serum treatment, which is the more effectual the prompter it is instituted. The technic of the gelo-diagnosis was described in No. 27 of the Bulletin (July 8). It is based on the relatively greater resistance of the typhoid bacillus to phenic acid, and the absence of fermentation of lactose. The suspected material is sown on appropriate culture media and gelose then inoculated with superficial colonies of the bacilli. They are then treated with phenic acid which destroys all but the typhoid and colon bacilli. These two germs are then differentiated by cultivating them on a medium containing lactose and litmus. The colon colonies are reddish, while the typhoid are blue. The diagnosis is completed by agglutination.

40. **Communication of Abscess with Bronchi.**—Bentz was treating an abscess in the right iliac fossa due to the production of pus in a tuberculous focus in the spine. Iodoformed vaselin was injected at various times, and a solution of hydrogen dioxid. After four months of this treatment, one day as the wound was being dressed the child coughed up a quantity of the foaming hydrogen dioxid, which was being injected in the iliac fistula. The phenomenon occurred only once, but the child has developed a tuberculous lesion in the lungs which had previously appeared to be sound. Fraenkel and Remy have published each a similar case of communication with the bronchus of an abscess appearing at a distance from the place where the pus is formed. Both children recovered. In Remy's case the child had had a vomica, but in the other cases no symptoms before or afterward indicated an opening into the bronchi. The small rupture in the wall must have closed spontaneously after the passage of the fluid, which was probably injected into the iliac or hip fistula with more force than was realized. Caution is necessary in making injections in a case where the location of the primary focus suggests possible communication with the air-passages.

41. **Technic of Spinal Cocainization.**—Tuffier has adopted the modification of using the patient's own cerebrospinal fluid as the vehicle for the cocain, but he considers it dangerous to mix them exposed to the air for fear of possible infection from germs in the air. He sterilizes according to Tyndall a sealed vial containing 4 cg. of cocain dissolved in 7 drops of sterilized distilled water. This makes a 12 per cent. solution. He breaks the tip of the vial and aspirates its contents into the syringe, allowing no air to enter with it. He then makes the lumbar puncture with the needle detached from the rest of the syringe. As soon as the cerebrospinal fluid is flowing through the syringe he adjusts the body of the syringe to the needle, and the cerebrospinal fluid flows into it, slowly pushing up the piston as it enters, until the receptacle is full, and blends with the concentrated solution of cocain already in it. He then injects the mixed fluid. The anesthesia does not extend so high as by his previous technic; it is of shorter duration, is slower in appearing and is less perfect, but on the other hand, the after-effects are infinitely less. He performed more than 1,200 operations of all kinds on the abdomen by his old technic, but with the new the radical operation for hernia is the highest intervention possible with the present method of anesthesia. For interventions above this he resorts to his former technic. He has been using the present technic for more than a year now, after thorough tests had established that the two fluids blend perfectly.

43. **Massage in Tabes.**—Costensoux regards massage in tabes as a general tonic, and a means of combating certain sensory troubles and certain complications. It must always be gentle and brief, as tabetic subjects are unable to bear fatigue, and for this reason massage of the muscles should be avoided. It should be restricted to the skin and should be done by a physician conversant with tabes or by a masseur strictly obedient to instructions. Passive mobilization of joints is contraindicated and active movements should be along the lines of re-education. All massage in tabes must be scrupulously individualized to the case, bearing in mind that what may benefit one patient may harm another.

44. **Eichhorst's Treatment of Diabetes.**—Romme reviews the results of Eichhorst's experience recently published (see The Journal, xxxix, p. 1217, title 93). He proscribes absolutely all medication and alcohol, and attributes but little if any value to mineral waters. He regards the diet as of paramount importance and adapts it to the individual case with frequent weighing to determine progress. He says that he would rather have a diabetic in good condition even at the expense of a little sugar in the urine, rather than to completely banish the sugar and have the patient growing thinner and weaker all the time. He does not alter the diet abruptly, but proceeds gradually, allowing for beverages weak coffee or tea, water or an alkaline water to which lactic or citric acid is added.

45. **Pathogenesis of Dorsal Tabes.**—Nageotte describes and illustrates the invasion of the nerve roots by the syphilitic meningeal inflammation which he has previously described under the name of interstitial transverse radicular neuritis. The radicular neuritis is not an inevitable but merely a frequent consequence of syphilitic meningeal lesions, but it invariably accompanies tabes. This radicular neuritis may also occur in the course of non-syphilitic affections.

48. **Radium for Lupus.**—Trémolières states that several of Danlos' patients treated more than a year ago have shown no sign of recurrence of the lupus. The radium is applied in the form of a powder in a small celluloid or rubber bag or sachet, containing a mixture of barium chlorid and radium chlorid. It is held in place over the lupus patch with a strip of gauze and left for six hours to five days. The area ulcerates in one to three weeks and heals with a smooth supple scar in twenty to twenty-five days. (See The Journal, xxxix, p. 728.)

55. **Typhoid Serotherapy.**—This communication from Chantemesse was hailed as marking an epoch when presented at the Egyptian Medical Congress which has just closed its sessions. Chantemesse compares the results of the treatment of typhoid fever during twenty months at all the hospitals of Paris with the results obtained by him at "Bastion 29" where he had 186 typhoid fever patients during the same interval. At the other hospitals the mortality was 286 in 1,192 cases, that is, an average proportion of 19.3 per cent. Even in the hospitals with the lowest mortality it never fell below 12 per cent. At Bastion 29, on the other hand, where the serum treatment was combined with balneotherapy, there were only 7 deaths, or a mortality of 3.7 per cent. in 186 cases. Three of the patients were practically moribund when received. To this 186 he adds the 70 reported last year, with 4 deaths, and the 100 of the year before, with 6 deaths, a total at Bastion 29 of 356 typhoid fever cases with an average mortality of 4.7 per cent. The method has also been applied in 151 cases at Toulon and even in inexperienced hands reduced the mortality to 13 cases. This brings the total to 507 cases of typhoid fever, all in adults, with 30 deaths, a total mortality below 6 per cent. One of the finest examples of the power of the serum is shown in the rapid healing of typhoid osteitis and periosteitis after local injection of the serum. He has witnessed several cases in which inflammatory osteo-perfostitis, suppurating for years, soon healed under the influence of a drop or two of the serum repeated every fifteenth day. The difference between the aspect of the organs of treated and non-treated animals is apparent even to the naked eye. In the latter, after inoculation of typhoid infection, the spleen and marrow are intensely congested, and the lymphoid apparatus exhibits a slight deleterious reaction. In the animals treated with the serum the spleen and marrow are likewise swollen, but the tumefaction is not caused by congestion, but by an enormous reactionary hypertrophy of the lymphoid and myeloid tissue. The corpuscles in the spleen are unusually large and the lymphatic cells unusually numerous. The trabeculæ are also in active reviviscence. The fat is absorbed, and the trabeculæ are crowded with a large number of young cells, generally with basophile protoplasm. Typhoid bacilli injected into the ear of a rabbit continue to grow and flourish as in a

culture medium. But if the animal has been injected with 2 or 3 c.c. of the serum a few hours beforehand, the majority of the bacilli are taken up by the phagocytes and rapidly destroyed. The effect of typhoid toxin, injected in the place of the bacilli, is neutralized in the same way by a previous injection of the serum. In short, the serum acts by stimulating to extra activity not only the phagocytes but also the apparatus which produces them, if the latter is still capable of responding to the stimulus. The serum is, therefore, most useful at the onset of the disease. After the system is saturated with the infection, the serum must be applied with caution and weak doses given not to do harm by the reaction invoked. Consequently experience and skill in its administration are required to judge of the proper dose when the disease is in an advanced stage. Even if the presumptive diagnosis of typhoid fever at the onset proves to be erroneous, and the patient is found later to be suffering from some other disease, no harm can follow the injection of a dose of 2 c.c. of the serum. Chantemesse always supplements serotherapy with balneotherapy, and considers the latter an indispensable adjuvant.

61 Le chlorure d'éthyle (ethyl chlorid) en anesthésie générale. H. Girard. (Commenced in No. 11.)

57. **Surgery of Heart.**—Terrier's address was reviewed in THE JOURNAL of Nov. 22, 1902, p. 1355.

57. **Treatment of Tetanus.**—Vallas' address was reviewed in THE JOURNAL of Jan. 3, 1903, p. 42.

60. **Simple Ulcer of Large Intestine.**—Quénu gives the details of 26 cases of simple ulcer which he has found in the literature, mentions 3 more of American origin, known only by title, and describes a case personally observed and 4 communicated to him by Tédenat. He discusses the history, etiology, pathology, symptomatology and treatment, assuming that simple ulcer, such as is common in the stomach, may occur at any point along the entire alimentary tract. The cause is undoubtedly a dystrophic condition of the intestinal wall due to lesions in the arterioles and these due in turn to some general intoxication of bacterial or other origin. An ulcer in the colon has no pathognomonic symptoms, but the existence of painful spasmodic constipation with a fixed pain, spontaneous and provoked, always the same, even in the midst of radiating pains, suggests a subjacent local lesion and differentiates the ulcer from simple constipation. Colitis, on the contrary, whatever its nature, is accompanied by a more diffuse pain and palpation is painful along the entire length of the intestine. In colitis, also, pus, false membranes, bloody slime, etc., may be noted in the stools in case of ulceration of the mucosa, but they are not found with simple ulcer on account probably of the small extent of the lesion. Experience to date indicates that slight hemorrhage locates the ulcer in the colon while severe hemorrhage locates it in the rectum. Whether the lesion thus located in the colon be an adhesion, a neoplasm or an ulcer, all require exploratory laparotomy, and in the latter case as prompt as possible to forestall perforation. Parker's patient had been treated for appendicitis six weeks before perforation of an ulcer in the colon. There are only five operations on record for simple ulcer of the large intestine, with three recoveries. The surrounding tissues are usually sound and treatment of a perforated simple ulcer may be restricted to suturing the edges together after turning them in. Resection of the edges does not seem to be necessary. In case the ulcer is merely suspected and has not perforated, simple invagination of the affected zone or economical resection of the ulcer is advisable if the aspect of the serosa allows its site to be determined. If the serosa is of normal aspect it is impossible to locate the ulcer from without. Perforation occurred in 19 of the 27 cases he reviews.

69. **Injurious Action of Salicylic Medication on Urinary Passages.**—Lüthje has been investigating the condition of the urinary apparatus after the ordinary therapeutic administration of the salicylates. He found that in every case without exception there were evidences of a desquamative irritation in the kidneys and urinary passages, and the bladder was also seen to be inflamed. The conditions did not return to normal until after an interval of two or three weeks. The urine invariably contained tube casts and cylindroids. There can be no question of an idiosyncrasy on account of the large number of patients examined (33), and the results of experimental tests. He therefore warns that the salicylates should never be given for more than three or four days and the daily dose not exceed 5 gm. even in acute articular rheumatism.

80. **Suffocation from Ascarides.**—The case was remarkable in that the child, a boy of 8, was under constant supervision in a hospital on account of scarlet fever. He had been given santonin and evacuated and vomited numbers of worms. A large clump was found after death in the entrance to the esophagus. A small amount of air could be breathed so that the intense dyspnea did not prove fatal until after two hours had elapsed.

84. **Chronic Tetanus.**—Grober has had occasion to observe a case of chronic tetanus similar to the three reported by De Brun from his practice at Damascus. The tetanic contractures persisted in the latter for three and four months and five years. Mastication and deglutition could be performed only with difficulty. Grober's patient was a lad of 12, who apparently recovered from a typical attack of traumatic tetanus under treatment with salicylate, narcotics and sweats. A month later the former symptoms recurred with no evidences of fresh infection and tonic spasms developed in arms and thighs. Various mus-

cles became chronically contracted, with risus sardonicus, the teeth rigidly set with a space of .5 cm. between them. Internal organs apparently sound. When first seen by Grober, nine months after the first symptoms, this condition still persisted. The upper part of the trunk is most affected, the shoulders drawn together, the patient unable to sit or turn over in bed. No antitoxin treatment was instituted as Grober assumed that the primary infection had induced a gradually extending myositis fibrosa, substituting the contractile tissue. No improvement has been noted in the two years since, except that the patient is less emaciated, and the arms are more easily moved. An attempt is now to be made with orthopedic apparatus.

87. **Cholangitis Calculosa.**—Mieczkowski reports that a patient at Mikulicz's clinic discharged 2300 c.c. of bile in twenty-four hours through the fistula left after a cholecystectomy on account of lithiasis. The urine diminished in quantity meanwhile to such an extent that uremia was indicated by the vomiting. The fistula soon healed.

89. **Serotherapy of Diphtheria.**—Wettstein states that the mortality from diphtheria at the Zürich clinic has been less by two-thirds during the last five years than previously. At the same time the mortality throughout the province has been scarcely one-half less, probably owing to the fact that antitoxin is not so readily procurable outside of the cities.

91. **Traumatic Gastric Ulcer.**—The experiments and four cases described by Gross indicate that a contusion affecting the stomach may be the starting point for an ulcer. But it does not develop unless the healing tendency in the subject is defective. Hyperacidity, of course, favors its development. The stomach may be injured while the abdominal wall and other organs are intact.

92. **Syphilis of the Viscera.**—The viscera are affected in about the same proportion in hereditary as in acquired syphilis. A syphilitic process in the stomach is in many points identical with that of a round ulcer. Its diagnosis is still a weak point. Bobrow's case has demonstrated the value of appropriate surgical treatment of syphilitic affections of the stomach too advanced to yield to mercurial treatment. Thirteen operations on the liver are on record, including the one described. The three deaths occurred in persons of 40 and over. In several cases the tumor was not resected when its syphilitic nature was discovered on operation. In others a gummatous tumor too large for spontaneous absorption was resected, or a lobe of the liver, which had become, as it were, "tied off." In one case a severe diarrhea which had persisted for eighteen months was cured in a week by mercurial treatment after its syphilitic nature was surmised. Trinkler has observed only 12 cases of syphilitic diarrhea in his practice. He is inclined to operate in case of syphilis visceralis as soon as mercurial treatment proves ineffectual. He has found that ascites may accompany gumma in the liver and be absent in case of cancer of the organ.

95. **Correction of Extreme Curvature of the Legs.**—Reiner incises the soft parts down to the bone and then cuts the bone nearly across at the deepest point of the concavity or inner angle. He then applies manual extension and later the extension screw. The results are surprisingly excellent in several cases he illustrates. In one each leg was shaped almost like a Z below the calf. He cuts the Achilles tendon if too resistant.

96. **Treatment of Perforation and Lacerations in Gall Bladder.**—Baldassari reports successful experimental results from the application to the defect of a flap cut from the abdominal wall near the incision. Such a flap contains a layer of serosa and also a layer of striped muscle which is turned toward the interior of the gall bladder. When the dogs were killed later the gall bladder showed merely a very slight depression at the spot. In the more recent cases the transplanted flap was moderately stained with bile. By using a flap of this kind the surgeon will be able to operate on the gall bladder with greater assurance, not hesitating to excise a part that is firmly fastened by adhesions or degenerated, knowing that the defect left can be easily remedied.

108. **Congenital and Infantile Myxedema and Endemic Cretinism.**—Pineles regards these conditions as three distinct entities. The first is liable to occur anywhere; the second is mostly confined to Great Britain and Belgium. These both affect the female sex mostly, while endemic cretinism shows a slight excess of the male sex. The first displays symptoms during the second half of the first year of life or later, while the second does not become manifest until after the sixth year, and cretinism is evident in the earliest childhood. The congenital variety is generally severe and causes marked disturbance in the growth, while the infantile variety is usually mild; cretinism may be either mild or severe. The thyroid gland in congenital myxedema is defectively developed, while in the infantile form there is atrophy of the gland, and in

cretinism there is strumous degeneration and occasionally atrophy. The etiology of congenital myxedema includes chronic alcoholism, tuberculosis or neuropathologic heredity and sometimes consanguinity. That of the infantile form includes the factors which determine idiopathic myxedema in adults. Endemic cretinism is due to some unknown infectious injurious influence. The so-called sporadic cretinism belongs in the group of congenital myxedema.

112. **Symptomatology of Angina Pectoris.**—Kaufmann has witnessed a number of cases in which the pains were more or less limited to the epigastrium and would have been diagnosed as a stomach affection by the inexperienced, notwithstanding the absence of nausea and vomiting. The success of treatment addressed to the assumed angina pectoris confirmed the true diagnosis. He explains the pains as the subjective perception of colic of the vessels emanating from arteriosclerotic lesions of the vessel wall, with which secondary radiating pains may be associated. As the bile duct or ureter contracts with a painful cramp above the point where a calculus is irritating its walls, the arteries are similarly liable to cramps of the same nature when lesions of an arteriosclerotic vessel become irritated by over-distension, increased pressure or vigorous vasodilation. As digitalis increases the blood pressure it only adds to the pains in such cases. Morphin arrests the attack by diminishing the sensibility of the point that is being irritated. Diuretin, on the other hand—like atropin in case of spastic contraction of the intestine—exerts an inhibiting, soothing action on the spastic contraction of the vessels and is the sovereign remedy in these cases. The gastric pains are distinguished by being brought on by physical exertion, change of position, etc., with no direct connection with eating; also by the localization of the pains and the influence of medication addressed to the circulation. The attack recurred in one patient whenever he lay down.

113. **Intermittent Angiosclerotic Dyspragia of the Intestines.**—Ortner reports a case of what he describes as a hitherto unobserved form of angiosclerosis of the intestinal arteries. The symptoms and cause were similar to those of intermittent claudication, as established by the autopsy. He therefore applies to the syndrome observed the term intermittent claudication, or the more general expression which can apply to all the organs, intermittent angiosclerotic dyspragia (painful functioning). It may be paretic, spastic or painful. The case described was of the paretic form. The attacks occurred two or three hours after a hearty meal and lasted for two or three hours. The patient, a man of 55, suffered from burning pains in the abdomen, shortness of breath and distension of the right lower part of the abdomen, with obstinate constipation. After two months all the symptoms ceased for a year, then recurred for a week every four months for a year or two, when the attacks became progressively worse and he succumbed to peritonitis. The autopsy disclosed severe sclerosis of the intestinal arteries.

155 Casuistico di neurofibromi multipli. P. L. Pellegrino.
156 Sulla presenza dell' anchilostoma nel pellagrosi. G. Binetti.

137. **Case of Suture of Heart and Lungs.**—Pomara's patient was too severely wounded for survival to be possible, but the prompt suture of the wound postponed the fatal termination for a few days. His incision and the resulting flaps differed from those hitherto in vogue, as the incision was in the shape of a reversed T, the base line 12 cm. and the perpendicular 6 cm. in length.

140. **Transplantation of Pancreatic Duct.**—Ardizzone transplanted the duct in dogs to a distance of about 50 cm. from its normal orifice in the small intestine. The specific gravity and amount of urine diminished, the feces increased in quantity and the proportions of nitrogen, fats, ash and organic substances. The animals showed marked oligemia when killed after long observation.

143. **Surgery of Uterine Cancer.**—Bossi thinks experience is demonstrating that irritation from any slight cause may transform a simple solution of continuity into a malignant growth. He therefore advises a plastic operation to cover such a lesion and states that in 1,000 patients with various lesions of the uterus, treated by curettement and a plastic operation on the cervix, not a single case of cancer has occurred. On the other hand, 21 cases of cancer have developed in 1,000 patients with similar uterine affections, treated by curettement alone, without a plastic operation. He hopes that the prophylaxis of cancer will be one of the questions on the order of the day at the next international congress of gynecology.

144. **Lime as Sputum Disinfectant.**—In Boni's tests lime in chunks did not disinfect the sputa even on long contact. Pulverized lime had an attenuating effect on the Koch bacillus, in the course of several days, but still some of the guinea-pigs succumbed who had been inoculated with the sputa after eleven days of contact. The pneumococci and other bacteria were rapidly destroyed by the lime.

147. **Blood Cells in Cardiac Defects.**—Regolo has been investigating a number of patients with various affections in regard to the presence of cardiac cells (Herzfehlerzellen). He found them frequently in cases of congestive affections of the broncho-pulmonary apparatus, even with the heart intact. They were constant in cardiac affections and were important for the diagnosis when masked by a respiratory affection. They were most numerous in case of a mitral defect.

151. **Snail Broth as Culture Medium.**—Mollusks contain the largest proportion of glycogen in their muscles, and consequently are peculiarly adapted for a culture medium.

152. **Subcutaneous Injections of Hydrogen Dioxid.**—Campanella reports a single experiment on a rabbit who was restored to health after profound asphyxia by the subcutaneous injection of a total of 50 c.c. of a solution of hydrogen dioxid. The control animal died in a few minutes. No inconveniences or disturbances of any kind were noted. He thinks that hypodermoclysis has the advantages without the disadvantages of the endovenous route for the life-saving administration of oxygen in severe cases of asphyxiation, bronchial cramps, emphysema, loss of compensation in cardiac affections and in what is called local asphyxia of the extremities.

New Patents.

Patents of interest to physicians, December 16, 23 and 30:

715748. Making acetic acid. Paul Boessneck, Glauchau, Germany.
716221. Hernial truss. Francis J. Hage, Sr., Goldsboro, N. C.
716040. Applicator. Wm. C. Holt, Oakley, Kan.
716240. Syringe. Thomas L. Jones, Kansas City, Mo.
716265. Blister plaster. Elbert W. McAllister, South Bend, Ind.
716304. Fountain syringe. James H. Stearns, Brooklyn.
716329. Antiseptic protector for telephone mouthpieces. Robert I. Willmarth, San Francisco.
36172. Design, hot water bag or similar article. Victor C. Van't Woud, Brooklyn.
716526. Syringe bulb. Richard H. Eddy, Providence, R. I.
716426. Syringe. Alcinous B. Jamison, New York.
716448. Movement cure apparatus. Gerald J. Macaura, Hartford, Conn.
716756. Surgeon's operating table. Timothy B. Powers, New York.
716474. Apparatus for manufacturing and dispensing carbonated beverages. Orrin J. Price, Detroit.
716789. Manufacturing chlorates. Richard Threlfall, Birmingham, Eng.
717072. Magnetotherapeutic apparatus. John Burry, Brooklyn.
717085. Casein compound. Henry V. Dunham, New York.
716878. Making caffein. Benjamin R. Faunce, Philadelphia.
717407. Ear-massage apparatus. Miller R. Hutchinson, Upper Montclair, N. J.
717436. Inhaler. Stephen A. Morse, Oklahoma, O. T.
716931. Nasal irrigator. Charles H. Pattison, Chicago.
717448. Sterilizing apparatus. R. R. Pease and P. J. Tucker, Hartford, Conn.
717474. Atomizer. George S. Tolman, Winthrop, and G. K. Jones, Somerville, Mass.

The Public Service.

Army Changes.

Movements of officers of the Medical Department, U. S. A., under orders from the Adjutant-General's Office, Washington, D. C., from Dec. 22 to Dec. 26, 1902:

Adair, Geo. F., contract surgeon, U. S. A., is relieved from further duty in the Division of the Philippines, and will report in person to the commanding general, Department of the East, for assignment to duty.

Anderson, Robert A., contract surgeon, U. S. A., is granted leave of absence for two months, to take effect about Jan. 1, 1903.

Brownlee, Chas. Y., first lieut. and asst.-surgeon, U. S. A., is granted leave of absence for twenty days.

Dale, Frederick A., first lieut. and asst.-surgeon, U. S. A., is granted leave of absence for ten days.

Edwards, James F., first lieut. and asst.-surgeon, U. S. A., is relieved from further duty in the Division of the Philippines, and on the expiration of his present leave will proceed to Ft. Leavenworth, Kan., for duty at that post.

Powell, Dwight C., contract surgeon, U. S. A., will proceed to Ft. Barrancas, Fla., and report to the commanding officer of that post for duty to relieve Captain Thomas J. Kirkpatrick, asst.-surgeon, U. S. A., who will proceed to San Francisco, and report to the commanding general, Department of California, for assignment to duty with troops en route to the Philippines.

Reynolds, Charles R., first lieut. and asst.-surgeon, U. S. A., now at San Francisco, will proceed to Ft. Washington, Md., for duty, relieving First Lieut. Frederick F. Russell, asst.-surgeon, U. S. A., who will proceed to Ft. Wingate, N. M., and report to the commanding officer of that post for duty.

Thorp, Chas. W., contract surgeon, U. S. A., will proceed to Ft. Grant, Ariz., to relieve Captain Charles E. B. Flagg, who will proceed to San Francisco, for assignment to duty with troops en route to the Philippines.

Van Poole, Gideon McD., first lieut. and asst.-surgeon, U. S. A., is granted ten days' extension of leave.

The following named officers, now at San Francisco, will proceed to their respective homes to await their honorable discharge from the service of the U. S., Feb. 1, 1903: Captains Robert E. Caldwell, Joseph L. Sanford, Percival S. Rossiter, Elmer S. Tenney, Wm. H. McPherson and Francis J. Pursell, asst.-surgeons, U. S. V.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ended Jan. 3, 1903:

Asst.-Surgeon J. M. Brister, detached from the *Frolic* and ordered to the *El Cano*.

Asst.-Surgeon U. R. Webb, detached from the *Iris* and ordered to the Naval Station, Cavite, P. I.

Asst.-Surgeon H. A. Dunn, detached from the *Vicksburg* and ordered to the *Frolic*.

P. A. Surgeon C. A. Crawford, detached from recruiting duty and ordered home to wait orders.

P. A. Surgeon G. L. Angeny, detached from the *Lancaster* and ordered to the *Essex*.

Asst.-Surgeon R. W. Plummer, detached from the Naval Hospital, Chelsea, Mass., and ordered to duty at Chattanooga, Tenn.

Asst.-Surgeon G. F. Freeman, detached from the *Essex* and ordered to duty at Naval Hospital, Chelsea, Mass.

Asst.-Surgeon W. H. Ulsh, Dec. 22, 1902, retired from active service, by reason of disabilities incurred in the line of duty.

P. A. Surgeon H. C. Curl, ordered to the Naval Hospital, Mare Island, Cal., for treatment.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ended Jan. 1, 1903:

Surgeon Preston H. Ballhache, leave of absence for seven days on account of sickness, under Paragraph 179 of the regulations.

P. A. Surgeon H. S. Mathewson, granted leave of absence for seven days from Dec. 2, 1902.

P. A. Surgeon S. B. Grubbs, detailed to represent the service at meeting of the American Public Health Association at New Orleans, Dec. 8-12; to proceed to Ensenada, Cal., for special temporary duty, Dec. 12, 1902; to proceed to Mazatlan, Mex., for special temporary duty, Dec. 30, 1902.

Asst.-Surgeon W. A. Korn, granted leave of absence for seven days from Dec. 25, 1902, under Paragraph 181 of the regulations.

Asst-Surgeon J. W. Schereschewsky, to proceed to Charleston, S. C., and assume temporary command of the service during the absence, on sick leave, of A. A. Surgeon F. F. Sams.

Asst.-Surgeon H. McG. Robertson, relieved from duty at Chicago, and directed to proceed to New York (Stapleton), and report to medical officer in command for duty and assignment of quarters.

BOARDS CONVENED.

Board convened at Washington, D. C., Dec. 26, 1902, for the physical examination of Chief Engineer Howison, R. C. S. Detail for the Board: Assistant Surgeon-General H. D. Geddings, chairman; Asst.-Surgeon B. S. Warren, recorder.

Board convened at Washington, D. C., Dec. 27, 1902, for the physical examination of Chief Engineer Maher, R. C. S. Detail for the Board: Assistant Surgeon-General H. D. Geddings, chairman; Asst.-Surgeon B. S. Warren, recorder.

PROMOTIONS.

John Achenbach and E. S. Maguire, to be pharmacists of the first class.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Jan. 3, 1903:

SMALLPOX—UNITED STATES.

California: San Francisco, Dec. 14-21, 7 cases.
Colorado: Denver, Dec. 6-20, 11 cases.
Illinois: Chicago, Dec. 20-27, 3 cases.
Indiana: Dec. 20-27, Evansville, 1 case; Indianapolis, 37 cases, 4 deaths; Kokomo, 1 case; South Bend, 1 case.
Kentucky: Lexington, Dec. 20-27, 1 case.
Maine: Portland, Dec. 20-27, 1 death.
Massachusetts: Dec. 20-27, Boston, 13 cases, 6 deaths; Somerville, 1 case.
Michigan: Detroit, Dec. 13-27, 93 cases, 1 death; Grand Rapids, Dec. 20-27, 8 cases.
Mississippi: Natchez, Dec. 23, 10 cases.
Missouri: St. Louis, Dec. 14-21, 26 cases.
Nebraska: Omaha, Dec. 20-27, 9 cases.
New Hampshire: Dec. 20-27, Manchester, 7 cases; Nashua, 8 cases.
New Jersey: Camden, Dec. 20-27, 1 case; Jersey City, Dec. 21-28, 1 case.
New York: Binghamton, Dec. 20-27, 1 case; Buffalo, Dec. 13-20, 2 cases.
Ohio: Cincinnati, Dec. 19-26, 15 cases; Cleveland, Dec. 20-27, 7 cases, 4 deaths; Toledo, Dec. 6-27, 24 cases, 2 deaths; Warren, Dec. 6-27, 5 cases, 1 death.
Pennsylvania: Altoona, Dec. 20-27, 1 case; Erie, Dec. 20-27, 3 cases; Philadelphia, Dec. 20-27, 25 cases, 3 deaths; Pittsburg, Dec. 20-27, 23 cases, 3 deaths; Warren, borough and county, Dec. 10-17, 5 cases.
South Carolina: Charleston, Dec. 13-27, 4 cases.
South Dakota: Sioux Falls, Dec. 20-27, 1 case.
Tennessee: Memphis, Dec. 20-27, 4 cases.
Utah: Salt Lake City, Dec. 11-27, 20 cases.
Washington: Tacoma, Dec. 15-21, 3 deaths.
Wisconsin: Green Bay, Dec. 21-28, 1 case; Milwaukee, Dec. 20-27, 5 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Nov. 29-Dec. 6, 24 cases.
Belgium: Brussels, Nov. 29-Dec. 6, 1 death; Ghent, Nov. 22-29, 3 deaths.
Canada: Winnipeg, Dec. 13-20, 1 case.
Great Britain: Leeds, Dec. 6-13, 6 cases, 1 death; Liverpool, Dec. 6-13, 34 cases, 1 death; Manchester, Nov. 29-Dec. 6, 3 cases; Sheffield, Nov. 29-Dec. 6, 5 cases.
India: Bombay, Nov. 25-Dec. 2, 2 deaths; Karachi, Nov. 23-30, 1 case.
Italy: Palermo, Nov. 29-Dec. 6, 6 cases, 2 deaths.
Malta: Nov. 23-30, 1 case.
Mexico: City of Mexico, Dec. 7-14, 2 cases, 3 deaths.
Russia: Moscow, Nov. 22-29, 2 deaths; Odessa, Nov. 29-Dec. 6, 5 cases; St. Petersburg, Nov. 29-Dec. 6, 13 cases, 2 deaths.
Straits Settlements: Singapore, Nov. 1-13, 5 deaths.

YELLOW FEVER.

Colombia: Panama, Dec. 8-22, 9 cases, 2 deaths.
Ecuador: Guayaquil, Dec. 6-13, 10 deaths.
Mexico: Vera Cruz, Dec. 13-20, 14 cases, 3 deaths.

PLAGUE.

India: Bombay, Nov. 25-Dec. 2, 120 deaths; Calcutta, Nov. 22-29, 12 deaths; Karachi, Nov. 22-30, 11 cases, 10 deaths; Madras, Nov. 22-28, 1 death.

CHOLERA.

India: Calcutta, Nov. 22-29, 42 deaths.
Japan: Osaka and Hiogo, Nov. 8-23, 3 cases, 2 deaths.
Straits Settlements: Singapore, Nov. 1-15, 22 deaths.

SURGERY OF THE STOMACH.

ARTHUR DEAN BEVAN, M.D.

CHICAGO.

It is the intention of this paper to present a brief review of the history and the present status of the surgery of the stomach.

Although gastrotomy for the removal of a swallowed knife was done as early as 1602 by Matthis of Brandenburg, and gastrostomy for stricture of the esophagus was done by Sedillot in 1849, the surgery of the stomach can very properly be said to date from Billroth's successful pylorectomy made in February of 1881. Stomach surgery, therefore, has reached its majority; it is twenty-one years old. It has reached a stage in its development which enables us to estimate its present value and draw conclusions probably approximating the truth. Let us very briefly sketch its history.

A BRIEF HISTORY OF STOMACH SURGERY.

Billroth's successful pylorectomy of 1881 was preceded by an unsuccessful attempt by Pean in 1879, and by Rydygier in 1880. In September of 1881 Wölfler suggested and performed the first gastroenterostomy by making an anastomosis between the anterior stomach wall and the jejunum. This is known as the Wölfler method. In 1882 Loretta introduced digital divulsion of the pylorus for benign stricture. In 1885 Von Hacker performed gastroenterostomy by making an anastomosis between the posterior wall of the stomach and the jejunum. Although Courvoisier had made a posterior anastomosis in 1883, the operation is known as the Von Hacker method.

In 1884 Charles T. Parkes of Chicago made a series of experiments on dogs, showing the feasibility of operative repair of both intestinal and stomach wounds, and this valuable knowledge was almost at once put to practical use. A short time after this Nicholas Senn introduced his decalcified bone plates for intestinal anastomosis, and these were used for a short period quite extensively in doing gastroenterostomy. In 1886 Heineke, and in 1887 Mikulicz, independently of each other, introduced pyloroplasty, which has since been known by their name, the Heineke-Mikulicz operation of pyloroplasty. In 1890 Bircher introduced the operation of gastroplication.

In 1892 Murphy introduced his anastomosis button, which has since then been very extensively used in stomach surgery, both here and abroad. In 1893 Frank introduced the now most generally employed method for gastrostomy. In 1894 Wölfler introduced gastroplasty and gastroanastomosis for hour-glass stomach. In 1894 Jaboulay performed the first gastroduodenostomy.

In 1897 Schlatter performed the first successful complete gastrectomy, although as early as 1883 Connor of Cincinnati had planned and unsuccessfully performed the operation. Comparatively recently Maydl has introduced the operation of jejunostomy as a palliative procedure in stomach carcinoma otherwise inoperable.

In 1880 Mikulicz, then an assistant of Billroth's, operated, but unsuccessfully, for perforating stomach ulcer. In 1892 Heusner operated for the first time successfully for perforating ulcer. Rydygier made the first successful excision of a gastric ulcer as early as 1881. Naturally in the early history of stomach surgery in the eighties and early nineties, the number of operations performed was small, but in the last five years especially this number has increased very rapidly, and we can now find a number of clinics where more than twenty-five stomach operations are done each year. My statements in this paper are based on a study of results of the work in these clinics where stomach surgery has been cultivated and my own rather limited work.

I desire to acknowledge my indebtedness to the reports from the clinics of Czerny, Mikulicz, Wölfler, Von Eiselsberg, on the Continent, the work of Mayo Robson in Great Britain, and W. J. Mayo, Nicholas Senn, John B. Murphy and E. Wyllys Andrews in this country, and for the medical aspects to Hemmeter, Osler and Fütterer. I am also indebted to the very instructive symposium on the surgery of the stomach presented at the American Surgical Association meeting of 1900.

In discussing stomach surgery let us do so under four heads:

1. Operations for malignant disease:
   - *a.* Pylorectomy.
   - *b.* Partial or complete gastrectomy.
   - *c.* Gastroenterostomy.
   - *d.* Jejunostomy.
   - *e.* Gastrostomy for malignant stricture of esophagus.
2. Operations for benign pathologic conditions, especially ulcer and its consequences:
   - *a.* Gastroenterostomy.
   - *b.* Partial gastrectomy; excision of an ulcer.
   - *c.* Repair of perforation.
   - *d.* Pyloroplasty.
   - *e.* Gastroplasty.
3. Operative treatment of:
   - *a.* Perforative wound of stomach.
   - *b.* Subcutaneous rupture.
4. Operative removal of foreign bodies. Gastrotomy.

OPERATIONS FOR MALIGNANT DISEASE.

Pylorectomy and Gastrectomy.—An analysis of results, both immediate and final, of operations done for malignant disease makes mournful reading, although

our improvement in technic has vastly bettered the immediate results as compared with those first obtained; the mortality is still large and the final results in gastroenterostomy and pylorectomy and partial and complete gastrectomy are such as to almost warrant the statement that all operations for malignant disease of the stomach are but palliative, and not curative in character. In view of this fact one is not surprised at the conclusions reached by Reginald Fitz in a recent paper on "Some Surgical Tendencies," in which he practically condemns operative treatment for malignant diseases of the stomach. One may, in the face of the facts, ask himself the question, is it worth while—the short questionable prolongation of life offered to these sufferers? Death is, after all, not always such a dreadful thing; may it not come to these poor victims of carcinoma as a blessing and relieve them from their sufferings? I have often asked myself in watching some of these cases, when I had prolonged the life for three or four months, have I not prolonged, not life worth living, but suffering for that period, and would it not have been better if I had not postponed the inevitable for the few months, but had let the patient pass away earlier with the euthanasia which morphin affords?

And yet, on the other hand, when I have had a patient who, after a pylorectomy for carcinoma, is relieved entirely of her symptoms and gains thirty pounds in weight, and beams with apparent restored health and the happy hope of cure, as I look at that patient I can not doubt that the surgeon's work was in that case worth the while. Following somewhat this line of thought, I have concluded that the hope of the future of stomach surgery for carcinoma lies either in some means to establish a diagnosis sufficiently early to enable the operator to remove widely and completely the disease, or more probably the cure of carcinoma by yet undiscovered means, and that for the present, aside from the necessary exploratory operation, to confirm or make the diagnosis, that operations for carcinoma of the stomach should be limited to such cases as permit of apparent entire removal of the disease, and these cases are at present few in number, and also that in a few well-selected cases a gastroenterostomy is warranted, cases where radical removal is not impossible and still where marked relief for a considerable period may, with some confidence, be expected. As a type of such a condition one might mention a case where there was marked obstruction of pylorus with invasion of surrounding organs preventing radical removal, and still with little invasion of the stomach tissue and with fair general condition of the patient.

Gastroenterostomy.—W. J. Mayo, of Rochester, Minn., who has probably done more work in stomach surgery than any other American surgeon, on analyzing his own results in 21 cases of gastroenterostomy done for carcinoma, says: "I regret to say that, with few exceptions, the palliation has been of such short duration as to hardly justify the operation," and he adds, "The hope of the future for cancer of the stomach is early exploration and extirpation."

Mayo Robson, the recognized authority in Great Britain on surgery of the stomach, in his excellent monograph on surgical treatment of diseases of the stomach, reports 23 gastroenterostomies for malignant disease; of these 10 died and 13 recovered; of these 13 5 are stated as living less than four months. In 8 cases the exact date of death was either not given, or is greater than four months; the longest period stated is nine months, and the reports from the Czerny, Mikulicz and other German clinics give about the same results. My own results in gastroenterostomy for malignant disease have given a large immediate mortality, and unsatisfactory palliation of short duration. Three deaths in eight cases, and short and unsatisfactory palliation in the other five. Chlumsky's statistics give a mortality of 41.6 in gastroenterostomy for malignant disease. When we turn to an examination of the results of pylorectomy and partial and complete gastrectomy for carcinoma, we again meet with discouragement, but with less discouragement possibly than in the results of gastroenterostomy for the same condition.

Analyzing the results of Krönlein, Maydl, Kocher, Rydygier, Czerny, Morrison and Mayo and my own, we find 190 cases, with 50 deaths, about 26 per cent.; 140 recoveries, about 74 per cent., and 17 cases who lived more than three years, about 8 per cent. Some of these, however, already presented recurrences, and some had died later than three years of recurrence, these facts cutting down the cases which we could accept as cured of carcinoma to about 5 per cent., or one in each twenty submitted to radical operation, and even here again comes the doubt as to diagnosis in some of the successful cases. Surely such a showing is one which must make the conscientious surgeon hesitate to urge surgical treatment to a patient suffering from carcinoma, on the ground that such treatment offered much hope of radical cure. The palliation, however, furnished by radical removal is more marked, more satisfactory and more lasting than that furnished by gastroenterostomy, and without doubt the operation produces in a small per cent. of cases a radical cure. Inasmuch, therefore, as the condition calling for relief is necessarily fatal, we are warranted in performing it, and we should not hesitate to advise it in the few carcinoma cases early diagnosed. We are forced to admit that the present-day surgical treatment of carcinoma of the stomach is not satisfactory, and leaves much to be desired; this statement applies, however, with almost equal force to carcinoma in general, and surely one of the greatest discoveries, let us hope that it will come soon, will be that of a successful treatment of malignant disease, and probably when it does come it will be on other than our present surgical lines.

Before leaving the subject of carcinoma, let me emphasize the fact that it is in early carcinoma very difficult for the surgeon, macroscopically, and at the time of operation, to make a differential diagnosis between this and other lesions, such as scar tissue and tuberculosis, and this fact adds sometimes to the difficulties of selecting the proper operative procedure, and also throws doubt on some of our statistics. Both Fütterer and Billings have recently emphasized the fact that carcinoma very often develops in an ulcer, and these cases naturally give a confusing picture, both to the medical diagnostician, as here we are apt to find free hydrochloric acid even in excess, and to the surgeon at the time of the exploratory operation. In some cases the surgeon at the time of operation may find no way of determining conclusively whether he has ulcer or carcinoma to deal with. Even the enlargement of the mesenteric glands can not be relied on as pointing to carcinoma, as Mayo and others have pointed out that we can and do have enlargement of these glands in simple ulcer and other benign lesions.

That mistakes are frequently made is demonstrated by the fact that not infrequently supposed benign obstructions which have been relieved by gastroenterostomy

die later of carcinoma, and, on the other hand, supposed malignant cases which have been supposedly merely palliated by a gastroenterostomy go on to permanent recovery, demonstrating conclusively the benign nature of the lesion.

The operation of complete gastrectomy has now been done a number of times since Schlatter's successful case. Mayo Robson collected from the literature 12 cases; of these 4 died as a result of the operation, and the earliest death of the other 8 was eleven months after operation. These results must be regarded as encouraging, and yet too much confidence should not be placed on these statistics, because without question many unsuccessful cases have not been reported. The operation has to-day a very limited field, and must be regarded as being still in the experimental stage.

Jejunostomy.—This procedure, which was advocated as a rival to gastroenterostomy, has little to recommend it. It certainly should not be employed where a gastroenterostomy would meet the indications, and the cases where the palliation of a jejunostomy is to be preferred to the palliation of morphin and rectal feeding must be extremely rare.

Gastrostomy.—A word in regard to gastrostomy for malignant disease of the esophagus and esophageal end of the stomach. From a limited experience and from an analysis of the literature, I believe that gastrostomy for malignant disease is seldom worth the while, and that the patient, if he could know both the palliation of rectal feeding, dilatation with a soft bougie and morphin on the one hand, and the dangers of the operation, with its almost equally short palliation and unsatisfactory existence, with the feeding through a gastrostomy fistula, on the other, would decide almost invariably against an operation.

OPERATION FOR BENIGN CONDITIONS.

Let us turn now from this glimpse of the distressing picture of carcinoma before which we have confessed the limitations of surgery, to the brighter picture of the surgical treatment of benign lesions of the stomach, and here we find one of the greatest triumphs of modern surgery.

Treatment of Ulcer.—Gastroenterostomy.—Let us review, in the brief time at our disposal, the surgical treatment of ulcer and its complications. Ulcer of the stomach occurs in from 2 to 5 per cent. of the population. The treatment of uncomplicated ulcer is distinctly medical, and probably 80 per cent. will recover under the modern rational medical treatment of rest and rectal feeding. In probably 20 per cent. the ulcer will persist in spite of treatment, or complications occur, either obstruction of pylorus, hour-glass contraction, hemorrhage or perforation. In this 20 per cent. surgical interference should be or must be employed. Uncomplicated ulcer of the stomach which resists properly employed medical treatment should be treated by a gastroenterostomy. The results are very satisfactory, both from the small immediate mortality, which is less than that to be expected from the uninterfered with lesion. Heydenreich states that the mortality from gastroenterostomy in these cases is 16 per cent., and the mortality from the disease 25 per cent. And, again, the patient is usually permanently cured by the procedure.

An argument in favor of the gastroenterostomy is advanced by Fütterer, in a recent article on the origin of carcinoma of the stomach, from chronic round ulcer, where he states that the dangers of a carcinoma developing in chronic ulcers are considerable, and this might be avoided by early gastroenterostomy with cure of the ulcer.

It would appear, at first glance, that a partial gastrectomy, removal of the diseased wall containing the ulcer, should be the operation of choice in these cases. Clinical experience, however, argues quite forcibly for gastroenterostomy; first, because excision of the ulcer gives a higher mortality, and, second, because the gastroenterostomy gives a higher percentage of cures so far as the relief of symptoms is concerned.

Pyloric Obstruction.—Of the three common complications of ulcer demanding surgical interference, obstruction of the pylorus with resulting dilation and often compensatory hypertrophy is the most important and frequent. An analysis of the literature demonstrates that here, again, gastroenterostomy has won for itself the position of the operation of choice. It has supplanted Loretta's divulsion, the Heineke-Mikulicz pyloroplasty and pylorectomy. The Loretta divulsion gave rather brilliant results, but they were but temporary, and such as we might expect; for just as a stricture of the urethra is temporarily relieved by the single passage of a sound and subsequent contraction occurs, so here the divulsion of the strictured pylorus was followed by relief of but short duration, and in almost all cases by subsequent recurrence. In the same way the Heineke-Mikulicz pyloroplasty has been largely discarded because in a considerable per cent. of the cases recurrence follows the rather brief relief of symptoms. The pylorectomy gives a larger mortality and not as good symptomatic cures as gastroenterostomy for benign obstruction of the pylorus, and is not to be employed except to meet some special indication.

Hemorrhage.—The second common complication of ulcer which demands sometimes surgical interference is hemorrhage. Hemorrhage, at the time of its occurrence, is to be treated medically by rest, both general and local, and the use of injections of normal salt solution and possibly combined with chlorid of calcium, with the idea that this may hasten the time of coagulation of the blood, which, in many of these patients, is distinctly slower than normal, and in this way aid in checking the bleeding. The shock present during and immediately following severe stomach hemorrhages is, as a rule, a clear contraindication against immediate operation, and clinical experience seems to show that the medical treatment offers the patient greater chances of recovery than surgical interference. However, a few surgeons advise immediate operation in severe hemorrhages. The choice of operative procedures lies between excision of the ulcer, ligation of the ulcer *en masse,* ligation of the bleeding vessel or vessels, cauterizing the ulcer and a gastroenterostomy. Of these, rather strange to relate, simple gastroenterostomy has given the best clinical results. The excision of the bleeding ulcer has given a high mortality. The ligation of the ulcer *en masse,* with the strengthening of the stomach walls at point of ulcer by Lembert suture, as advised by Andrews, seems a rational procedure, and one which has given fair results in the few cases in which it has been employed.

Rodman collected 13 gastroenterostomies for hemorrhage, with 3 deaths, or 23 per cent. mortality. The analysis of the reported cases would seem to favor the following procedure in cases of hemorrhage demanding an immediate operation: First, a gastrotomy utilized for locating and cauterizing the ulcer. As suggested by E Wyllys Andrews, in *Annals of Surgery,* 1899, the greater part of the stomach can be passed in review be

fore the anterior gastrotomy incision by passing two fingers through the gastrocolic cmentum and invaginating the stomach wall into the incision. Then the gastrotomy can be utilized in making a gastroenterostomy. In by far the greater number of cases of hemorrhage, inasmuch as Rodman's statistics show that but 8 per cent. of the cases which bleed die, the treatment of election would seem to be a gastroenterostomy, done in the interval between attacks, when the patient was free from shock. When done at this time, the operation gives very satisfactory results, both immediate and permanent, inasmuch as the gastroenterostomy is usually followed by the healing of the ulcer. Some of these patients suffer from profound secondary anemia. I have had one such case, where the hemoglobin find was but 19 per cent. In such cases a preliminary treatment by rest and rectal feeding, salt solution and iron and chlorid of calcium should be employed for three or four weeks, bringing, if possible, the hemoglobin find above 35 per cent. before operation.

Repair of Perforation.—The third complication of gastric ulcer which I shall discuss is that of perforation. This is a rare complication as compared with stenosis and hemorrhage. Finney has collected 268 cases in the literature which have been operated on; of these 139 recovered and 129 died, giving a mortality of 48 per cent., and of the 21 more recent cases 13 recovered and 8 died, a mortality of but 38 per cent. Tinker's statistics give a mortality of but 16 per cent. in the cases operated on early within twelve hours, and reported within the last three years. This must be regarded as a most brilliant showing, when we remember that without surgical relief perforating gastric ulcer gives a mortality approaching 100 per cent., and that practically we are entitled to regard each case recovering under surgical operation as a life saved by the procedure. The picture of perforation is, as a rule, one easily recognized, both by the competent internist and the competent surgeon, and if it is confusing, it is only to be mistaken with other serious lesions, such as acute pancreatitis and rupture of the bile tracts, which also call for immediate operation. A careful analysis of the facts demands an immediate exploratory operation in cases of suspected perforation of stomach ulcer. Frequently this can best be done under infiltration anesthesia. In the single case of stomach perforation on which I have operated I employed a general anesthetic, ether. I operated within five hours after perforation, and, in spite of the fact that the patient was in extreme shock and that the general peritoneal cavity contained at least a quart of stomach contents and peritoneal fluid, the patient made an uninterrupted recovery. The method of procedure will vary with the conditions found, but as a general proposition will consist of locating the perforation and closing the opening, without resection of the ulcer, with a double row of Lembert sutures, and then, if the condition of the patient warrants, a gastroenterostomy is made with the purpose of permanently curing the lesion. The escaped fluids are removed by irrigation of the peritoneal cavity with warm salt solution, and closure of the abdominal wall with, as a rule, provision for drainage down to the point of closure in the stomach wall, and often of the general peritoneal cavity. A discussion of the many complications of perforating gastric ulcer, such as perigastric abscess and subphrenic abscess, empyema, phlebitis, etc., would require more time than we have at our disposal. I would refer you to Mayo Robson's paper, read last year by invitation before the American Surgical Society, for a clear exposition of these subjects.

Hour-Glass Contraction of the Stomach.—Gastroplasty.—This condition may be congenital or the result of contraction following ulcer or other lesion. The condition is one usually not diagnosed before operation, as the symptoms resemble closely those of obstruction of the pylorus. I have operated on but one such case, and am rather inclined to believe that in that case I had to deal with a simple ulcer occurring in a case of congenital hour-glass stomach. Where hour-glass stomach produces symptoms warranting surgical interference, a gastroplasty or gastroanastomosis establishing a very free communication between the two stomach pouches, combined with gastroenterostomy, where we find evidences of obstruction of the pylorus also present, is the procedure indicated. Watson has collected from the literature 20 cases of congenital hour-glass stomach; 20 cases of hour-glass stomach of the acquired type not operated on, and 29 cases of hour-glass stomach submitted to operation. Of these, 3 were handled by a gastroenterostomy, no deaths; 17 gastroplasty, with 3 deaths; 6 cases, a gastroanastomosis, 1 death; inversion of ulcer, 1 case, 1 death; establishing gastric fistula, 1 case, 1 death. The gastroplasties referred to are practically made on the same principle as the operation of pyloroplasty, and the gastroanastomoses are practically lateral anastomoses between the two pouches. After a careful analysis of the reported cases, including his own, Watson concludes that gastroanastomosis should be the operation of choice.

OPERATION FOR WOUNDS AND RUPTURE.

Let us now turn to the surgery of perforating wounds of the stomach and subcutaneous rupture of the stomach.

Perforating Wounds.—Immediately following the experimental work of Charles T. Parkes, in 1884, and the work of Nicholas Senn, which shortly followed, surgeons generally accepted the dictum that all perforating stomach wounds should be immediately submitted to operative repair, and for some years little exception was taken to this opinion. An analysis of this subject, especially in view of the experience obtained by military surgeons in our late Spanish war and in the present South African war, has compelled us to adopt a somewhat different view of these cases. We were for a while working under the mistaken view that penetrating wounds of the stomach were so generally fatal that the cases recovering under operative procedures were to be regarded as cases saved. The Spanish and South African wars have shown conclusively the fallacy of this reasoning, because the perforating stomach wounds made by the modern military rifle, carrying a small-calibered bullet with great velocity, have not been very fatal; when let alone, the large majority of the cases recovered, but when operated on the large majority died. We can, therefore, no longer accept the dictum that penetrating wounds of the stomach must be immediately operated on. At least, this rule can not be applied to military practice. In civil practice, as a rule, bullet wounds of the stomach are made with revolver bullets, made of soft lead and of low velocity; these produce a more ragged wound with greater danger of leakage than the metal-jacketed, small-calibered, high velocity bullet of the modern military rifle, and from this fact most of the surgeons, who have studied closely the facts, still advise an immediate exploration in penetrating wounds occurring in civil practice. Personally, I am inclined to accept the same views, and yet we must admit that the treatment of penetrating wounds of the stomach can no longer be regarded as a closed chapter,

and that it is quite possible that a wider experience will limit still further operative treatment in these cases.

Subcutaneous Rupture of the Stomach.—This is a condition which calls for immediate operative repair, provided that the traumatism causing the rupture has not produced other serious lesions which make any interference hopeless. A few cases of rupture of the stomach from over-distention are reported, most of them found at postmortem; if diagnosed the indications for operation are, of course, imperative. A few cases of acute ulcer following trauma have been noted. Rupture of the stomach may be limited to one or more of the layers of the stomach walls, and occur without extravasation of the stomach contents. An interesting case of this kind was recently reported at the Chicago Surgical Society by Carl Beck, where, as a result of trauma, a cicatricial stenosis of the pylorus demanded a gastroenterostomy.

OPERATION FOR FOREIGN BODIES.

Lastly, perforations of the stomach may be caused by the passage of esophageal bougies, sword-swallowing, and from the accidental or intentional swallowing of knives, nails, screws, pieces of glass, etc., as has occurred in the insane and among the museum performers who make a business of swallowing such articles. In this same connection should be mentioned the operative removal of swallowed and retained foreign bodies which give rise to symptoms. My own experience has been limited to a single case of this kind, where a gastrotomy for the removal of a swallowed hat-pin was easily performed. It is in such cases that the *x*-ray can be employed with great advantage in making a diagnosis. In my own case I tried to convince the parents of a three-year-old child that it was impossible for the little patient to swallow a rigid steel hat-pin six and a half inches in length. The *x*-ray, however, showed the pin clearly, the head being in the stomach and the shaft in the esophagus. The experience with the Murphy button has taught us one interesting fact in regard to foreign bodies in the stomach, and that is that they may be tolerated for years without producing any injury or any symptoms. A large proportion, from one-fourth to one-half, of the Murphy buttons used in performing gastroenterostomy fall back into the stomach and remain there permanently; out of the now hundreds of cases in which this has occurred, very few have given rise to any disturbance or symptoms. In view of this fact we should hesitate to urge a gastrotomy for a foreign body, such as a tin whistle, or coin, or other body of smooth contour, which was not giving rise to symptoms. However, the operation of gastrotomy for the removal of a foreign body, where no complications exist, can be done with but slight risk to the patient.

THE OPERATIVE PROCEDURES DESCRIBED.

The technic of the operative procedures employed in stomach work has reached a stage of development which, although not perfect, is very satisfactory; so satisfactory, indeed, that the old great danger of this work, i. e., peritonitis, has been largely eliminated. Let us describe the purely surgical management of these cases under the following heads:

1. Preliminary preparation of the patient.
2. Question of anesthesia.
3. Operative technic.
4. After-treatment.
5. Complications.
6. Causes of death.

Preparation of the Patient.—The preliminary preparation of the patient involves, in addition to that necessary for other laparotomies, two special points. First, the point already referred to, that many patients demanding stomach operations are the victims of severe secondary anemia, and in these cases, where the hemoglobin find is below 35 per cent., if there is any possibility of increasing it to this point, or above, by three or four weeks of iron feeding and rest, this should be done before attempting the operation. In cases of benign disease this is usually possible. In cases of malignant disease, such secondary anemia usually shows that the case is inoperable, and when it is still operable, such attempt to correct the secondary anemia means usually valuable time wasted.

The second point in preliminary preparation is most important, and it is the complete emptying of the stomach immediately before operation. This must never be omitted, if possible, and must be most thoroughly carried out by competent hands. I have lost one case on the operating table because this step in the preparation, although attempted, had not been successfully performed. While the patient was being anesthetized she vomited large quantities of material from a greatly distended stomach, and drowned herself in spite of every effort to resuscitate her. A number of similar cases are reported, and this must be regarded as a quite possible accident, and must be most carefully guarded against. In addition to the dangers of drowning, a considerable amount of fluid in the stomach at the time of operation adds to the difficulty of keeping the peritoneal cavity clean and to the dangers of peritonitis.

The Question of Anesthesia.—Shall we employ a general or a local anesthetic? For a time a number of surgeons were rather enthusiastic over the use of infiltration anesthesia in stomach surgery, and some still are. There can be no question but that it is fairly satisfactory, and can fairly claim a certain limited field for itself. However, the special reason advanced for its employment in stomach surgery has been shown by trial to be erroneous, i. e., that it would eliminate the occurrence of one of the chief causes of death after stomach operations—pneumonia. Surgeons were inclined to regard these pneumonias as aspiration, chloroform and ether pneumonias. A considerable trial with the local anesthetic has shown, however, that fully as many pneumonias develop after operations done with cocain as after operations done under general anesthesia. This is certainly a very interesting fact, and leads one to the conclusion that these pneumonias are to be regarded as terminal infection pneumonias, made possible by the lowered resisting powers of the patient, and not to the use of a general anesthetic.

The operative technic can be fairly fully presented if we describe the technic of gastroenterostomy, pylorectomy, gastrostomy and gastrotomy.

Technic of Gastroenterostomy.—In gastroenterostomy the questions to be answered are, shall we use suture or button, and shall we make an anterior or posterior operation? I quite agree with Mayo, it does not make much difference, provided the operation is well done, whether we use button or suture, or whether we make an anterior or a posterior operation. My own preference, however, is an anterior operation with suture, and for these reasons: First, the anterior operation is the simpler and easier, and, as has been so well emphasized by Mayo, if we make the anastomosis at the lowest point of the anterior wall of the stomach, close to the greater curvature, the opening will be at about the same point as

a properly made posterior anastomosis, and will be at the lowest point of the stomach, thus securing the best drainage. I employ suture because, in spite of the fact that such excellent results have been obtained with the button, my analysis of the literature shows that now equally good results are being obtained with the suture. Again, in spite of the fact that a button retained in the stomach seldom gives rise to symptoms or complications, it nevertheless does sometimes do so, and as stated we know that from 25 to 50 per cent. are permanently retained. Again, the argument of saving time by the use of the button no longer carries very much weight, as with a little practice the anastomosis with suture can be made in about fifteen minutes. The argument that an anterior anastomosis is more apt to be complicated with the development of a "vicious circle" does not seem to be borne out by the comparison of cases of anterior anastomosis made at the lowest point with posterior anastomosis. In the early history of gastroenterostomy, when most of the cases were anterior operations, the mistake was made of making the anastomosis about midway between the lesser and greater curvatures, and as we might now expect a considerable number of cases develop vicious circle.

Taking all the facts into consideration, the simplest and best method of making a gastroenterostomy is to make the anastomosis between the lowest anterior point of the stomach and the jejunum, about eighteen to twenty inches from its beginning; unite three and a half inches of the bowel to the stomach; this prevents angulation and spur formation; make the opening one and a half to two inches in length; unite with two layers of continuous suture, the first layer including all the coats of the bowel, the second a continuous Lembert suture; silk, not too fine, seems preferable, although I can see no objection to using fine catgut for the Lembert suture. The two rows of simple continuous sutures, the first including all coats, the second a Lembert, to my mind, have solved the problem of all stomach and intestinal wound closure. Such continuous sutures are very easily applied; they effectually guard against leakage, and they bring all the layers into accurate approximation. The interrupted suture has no place in stomach work. It is difficult to employ it. It does not guard against leakage effectually, and, as often used, does not approximate the mucosa accurately, and the clinical results obtained are distinctly bad as compared with the results secured by the continuous suture. Whether an enteroanastomosis should be made is a question which has been answered in the affirmative by the Wölfler clinic. Personally, I have not employed it. Mayo says on this point: "In the future we will make an enteroanastomosis in every case in which gastroenterostomy is performed, if there is no obstruction to the pylorus." He comes to this conclusion from an analysis of his own cases, which showed that "vicious circle" developed only in those cases where the pylorus was not obstructed, and did not occur in any case of distinct obstruction. I am inclined to believe that his point is well taken, and shall give his advice a trial. The Y-shaped gastroenterostomy of Roux is anatomically the more perfect operation; it has, however, the great disadvantage of being long and tedious and is not therefore to be generally recommended.

Technic of Pylorectomy.—In making a pylorectomy we have practically the choice between the Kocher and the second Billroth method. I regard the second Billroth method as the operation of choice, because it enables us to remove the lesion as extensively as we may desire, and is easy of performance. After ligating off the omentum above and below the pylorus to the desired extent the portion to be removed is included between clamps and the duodenum and stomach beyond are closed with clamps. The duodenum is closed by invagination with a purse-string suture, and the stomach closed with the double layer of continuous suture above described. The simple anterior gastroenterostomy is then made, completing the operation. The Kocher pylorectomy has given excellent results, but it can not well be employed where a great amount of stomach tissue is removed. In the Kocher operation the diseased pylorus and portions of duodenum and stomach are removed, the stomach wound closed by two rows of sutures and the duodenum approximated to the posterior wall of the stomach, making an end-to-side anastomosis.

Technic of Gastrostomy.—The gastrostomy of Frank, made by pulling up a nipple-like process of the stomach through an opening in the split rectus, suturing the base of the process to the peritoneum and sheath, and bringing the apex out through a small opening in the integument an inch removed from the original incision, gives excellent results, both from the standpoint of immediate mortality and from the standpoint of obtaining a fistula lined by epithelium, and one which will not leak. It is the operation of choice. In some cases, however, it can not be used, as the stomach is too small and contracted. Here either the Senn method or Witzel method of obtaining a competent fistula should be employed.

Technic of Gastrotomy.—Little need be said of the technic of gastrotomy, but I think that little of importance; it is simply the advice to use the double row of continuous sutures in the closure.

After-Treatment.—The after-treatment to be employed in all cases of stomach surgery, except gastrostomy, should be rest to the stomach, obtained by rectal feeding for, if possible, six or seven days. Four ounces of peptonized milk every four hours and twelve ounces of salt solution every four hours, alternating injections therefore every two hours. As a rule, these are well borne. If they are not, however, liquid diet in small quantities can be begun earlier. I am inclined to believe this is the safer plan, although some surgeons begin feeding as soon as they recover from the effects of the anesthetic. The recumbent position is to be maintained, as a rule, for twelve days. Some surgeons adopt a semi-recumbent position, with the idea that it will reduce the dangers of pneumonia. The point is well worth consideration. Mayo uses buried silk in closing the abdominal wound in malignant cases, and allows the patient to sit up within a day or two and leave the hospital within a week.

The most frequent causes of death in stomach surgery are pneumonia, vicious circle, peritonitis, perforation of carcinoma or ulcer, shock and drowning from vomited stomach contents. Our time will hardly permit an analysis of these conditions, an example of each of which has occurred in my own work. Let me here merely call attention to this surprising and interesting fact, that in clinics where stomach surgery is extensively practiced peritonitis is no longer the common cause of death, but is, in fact, an unusual accident. This fact shows clearly the high degree of efficiency against leakage reached by our present methods of closure of stomach and intestinal wounds.

CONCLUSION.

Permit me, in closing, to make a plea for a wider application of surgical procedures to lesions of the stom-

ach. Disappointing as is the surgery for malignant disease, yet it is to-day our only ray of hope in these cases. Certainly the surgery of benign lesions has given us brilliant results and accomplished much good. It is capable of doing much more good than it is doing to-day. In almost every community cases of ulcer of the stomach die from obstruction, perforation or hemorrhage, which could be saved by timely operative procedure. These cases are entitled to the benefits of modern surgery, and they can obtain it if the surgeon can convince the general practitioner of the possibilities for good in such radical treatment. These cases are on the borderland between medication and surgery, and the best results, the greatest good can be obtained only by the helpful co-operation of the surgeon and physician; not by indiscriminate operating, nor by protracted routine medical treatment, but by the judicious selection of the treatment required to cure the individual case.

ACUTE ARTICULAR RHEUMATISM.

THE STATISTICS OF A SERIES OF 270 CASES FROM THE SERVICE OF DR. OSLER IN THE JOHNS HOPKINS HOSPITAL.*

THOMAS McCRAE, M.B., M.R.C.P.
Associate in Medicine, the Johns Hopkins University, and Resident Physician, the Johns Hopkins Hospital.
BALTIMORE.

The cases in this series are those of acute articular rheumatism which have been admitted to the medical service of the Johns Hopkins Hospital during a period of thirteen years (1889-1902). During this period the total medical admissions were 14,567, and of these 294 were for acute rheumatism, which equals practically 2 per cent. These 294 admissions represent 270 patients, some of them being admitted several times in different attacks. During the same period there were 54 cases diagnosed as subacute rheumatism, 39 as chronic rheumatism, 35 as gout, and 86 as arthritis deformans. The figures from the Montreal General Hospital have been sent me by Dr. Campbell Howard. In a period of 10 years (1891-1901) among 9,992 medical admissions there were 388 for acute articular rheumatism, which equals 3.8 per cent. During the same time there were 154 cases of subacute rheumatism. A comparison with the figures of some of the London hospitals is interesting. In St. Thomas' Hospital, during a period of ten years (1890-1899), there were 18,998 medical admissions, of which 997 were for acute rheumatism, which equals 5.2 per cent. In St. Bartholomew's Hospital, for a period of thirteen years (1888-1901), there were 31,085 medical admissions, of which 1,241 were for acute rheumatism, nearly 4 per cent. Church[1] gives figures for various London hospitals which give the proportion of acute rheumatism as being from 3.5 to 7 per cent. of the total admissions. There is probably little doubt that this disease occurs less frequently with us than it does in England. It may be said that in this series any doubtful case has been classified as subacute rheumatism.

INCIDENCE.

Sex.—Among the 270 cases there were 198 males and 72 females, a proportion of 2.7 to 1. This is almost exactly the proportion of males to females in the medical admissions.

Color.—There were 223 white and 47 colored, a ratio of 4.8 to 1. The proportion in all admissions of white to colored is about 7 to 1.

Age.—The number of cases and percentage in each decade are as follows:

Age.	Cases.	Percent.	Age.	Cases.	Percent.
1-10	7	2.6	41-50	36	13
11-20	70	26	51-60	15	5
21-30	93	34	61-70	3	1
31-40	46	17			

It has to be kept in mind that we have a comparatively small number of children admitted to the wards. Nearly 20 per cent. of the patients were over 40 years of age. The oldest patient was aged 66 years.

Occupation.—Only 93, or 36 per cent., worked out of doors and were therefore usually exposed to weather. This group comprises laborers, drivers, stevedores, etc. Of the others, 25 per cent. of the total were engaged in house work, 11 per cent. were mechanics, carpenters, etc., 10 per cent. were attending school, 10 per cent. were barbers, tailors, etc., and only 8 per cent. were in the higher walks of life, merchants, etc.

Time of Year.—The incidence in the various months is as follows:

Month.	Cases.	Percent.	Month.	Cases.	Percent.
January ...	23	8.5	July	19	7
February ..	36	13.3	August	11	4
March	35	12.9	September .	8	3
April	38	14	October ...	11	4
May	39	14.4	November ..	11	4
June	22	8	December ..	17	6

It will be noted that 55 per cent. of the cases occurred in the four months, February, March, April and May, and that three-quarters of the total number were in the first six months of the year. This is in direct contrast to the figures from the London hospitals, where, as Church points out, the maximum is in the autumn months, September, October and November. Prevalence in the spring months has been noted in Montreal by Howard.[2]

Family History.—A family history of rheumatism was given in 69 cases, which equals 25.5 per cent. It was about equal on the father's side, mother's side and in the immediate family. No special relationship between a family history of rheumatism and an especially severe attack could be made out. There was a family history of tuberculosis in 39 cases, which equals 14.5 per cent. Rheumatism and tuberculosis were associated in the family history in 12 cases. There was a family history of gout in 2 only. Of course, it is to be kept in mind that a family history of "rheumatism" might be more correctly termed one of arthritis. Other than true rheumatic arthritis is usually included by patients under the general heading of rheumatism.

Previous History.—This was practically negative in 66, or 25 per cent. There was a history of previous acute articular rheumatism in 121, or 45 per cent. Patients had tonsillitis previously in only 10 instances, which equals 3.7 per cent., and gave a history of chorea in only 7 instances, which equals 2.6 per cent. There was a previous history of both tonsillitis and chorea in only one instance. These figures appear to be rather small when we consider the generally accepted view that tonsillitis and chorea are so intimately associated with rheumatism. There was a previous history of lues in 12 cases. Fairly marked alcoholic history was given in a rather large number, nearly 39 per cent., all of whom had been moderate or heavy drinkers. It is of interest to note that a very much larger percentage of all our cases of gout gave a marked alcoholic history. The number of the attack with which the patient was first admitted is given as follows:

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank A. Jones, George Dock and J. M. Anders.

1. Church: Allbutt's System of Medicine, vol. iii.

2. Howard: Pepper's System of Practical Medicine, vol. ii.

Attack.	Cases.	Percent.	Attack.	Cases.	Percent.
First	140	52	Fifth	3	1
Second ...	72	26.6	Sixth	1	.3
Third	26	9.6	Uncertain ..	18	6.6
Fourth ...	10	3.7			

It will be noted that 52 per cent. of our cases were admitted with the first attack. In the cases from St. Thomas' Hospital previously noted, 54 per cent. were admitted with the first attack and 27 per cent. with the second attack.

Age at the Time of First Attack.—This was known definitely in 255 cases. It will be seen that in three-quarters of the patients the first attack occurred below the age of 30. It is interesting to note, also, that in over 11 per cent. the first attack occurred after the age of 40. In 3 per cent. the first attack was over the age of 50, which is to be noted in connection with the statement sometimes made that acute articular rheumatism never occurs for the first time after the half century is passed. In our oldest case the initial attack was at the age of 66. The figures are as follows:

Age.	Cases.	Percent.	Age.	Cases.	Percent.
1-10	22	8.6	41-50	22	8.6
11-20	93	36.4	51-60	7	2.7
21-30	76	29.8	61-70	1	.3
31-40	34	13.3			

Complaint Made by the Patient.—Arthritis was complained of by 167, "rheumatism" by 84, various other symptoms by the remainder. It is of interest to note that of these 6 complained of sore throat; 2 of chills and 2 of chorea.

Onset.—There was a definite history of exposure to wet or cold immediately before the onset of the attack in 32 cases, or 12 per cent. Arthritis was the first symptom noted by the patient in 194 cases, or 82 per cent. Chills at the onset occurred in 18 cases, practically 6 per cent. This is rather an interesting point, as little stress is usually laid on chills at the beginning of rheumatic fever. Tonsillitis was the symptom of onset in 10, in only one of which was it associated with chill. Various other symptoms were first noted in a few cases, such as fever, sweating, nose bleed, skin rash, etc. There was only one instance in which trauma was an apparent etiologic factor. This patient was struck on the shoulder by a piece of timber and was severely injured. The next day other joints were involved with arthritis, but not the injured one, which escaped entirely.

SYMPTOMS.

Arthritis.—This, of course, was by far the most prominent symptom and was present in every case of the series. It is of interest to note the relative frequency with which the joints were involved. Taking all the cases the knee was involved far more frequently than any other joint, viz., in 142 cases, or 53 per cent. The ankle was next, in 88 cases, or 33 per cent. As is usually the case, the lower extremity was involved more frequently than the upper extremity; in this series in a proportion of about four to three. The order of frequency of involvement of the joints is as follows: knee in 142, ankle in 88, shoulder in 75, wrist in 62, elbow in 54, hip in 52, the hand in 47 and the foot in 42 instances. It is interesting that in all the joints of the lower extremity both sides were more often involved than one alone; for example, in the case of the knee more patients had both knees involved than one. In all of the joints of the upper extremity the contrary was the case; one wrist, for example, was much more often involved than both. Fluctuation was noted in the joints in 47 cases.

Fever.—The average duration of fever in 254 cases was 12 days. It is, however, to be kept in mind that a certain number of the cases were admitted late in the disease, and in some of these the fever dropped very rapidly after admission. The fever persisted for a period of over four weeks in 26 patients, the longest duration being ten weeks, which occurred in two patients.

In studying the temperature records there are two types of cases which rather stand out, as has been noted before in studies of series of cases, those in which the temperature is perhaps at an average of about 103 for a few days and then rapidly goes down to normal, and those in which the temperature is never so high, perhaps averaging only 101, but continues elevated for a very much longer time. The joint symptoms in these two cases may be identical. In many cases these persisted after the temperature had fallen to normal. There was no instance of hyperpyrexia in the series. In only 10 cases was the fever above 104. In only 29.5 per cent. did it reach 103 or over. This leaves 70.5 per cent. of the cases with a temperature not above 102.5. There is a fairly general impression among those who have had hospital experience, both in the north and in Baltimore, that the general type of rheumatic fever in the latter place is not so severe. Certainly one does not see the very severe acute types of the disease so frequently as in the north.

There are various symptoms of common occurrence, such as general malaise, loss of appetite, sweating, constipation, etc. These require no special consideration.

Cardiac Conditions.—These, of course, are of special interest and are worthy of being considered in some little detail. It is convenient to divide the cases into three groups: (1) those cases in which the heart sounds were clear throughout; (2) those in which there was no question of the presence of an organic cardiac lesion, and (3) a group of doubtful cases in which it is very difficult to say how much cardiac involvement was present.

1. *Cases with Clear Heart Sounds.*—Of these there were 100, or 38 per cent. In 86 of these there was throughout no departure from normal conditions. In 6 there was a reduplication of the second sound at the base on admission, but no murmurs were made out at any time. In 4 there was reduplication of the second sound at the apex on admission, but no murmur was made out at any time. In 2 there was pericarditis, but the sounds were unchanged; in 1 there was gallop rhythm on admission, and in 1 marked irregularity of the heart's action on admission, both disappearing later. As these cases were all discharged with perfectly clear heart sounds and no other signs of cardiac involvement they may be regarded as practically having escaped. Of course, it may be said that myocarditis was present in the cases with gallop rhythm or marked irregularity. This may be the case, but on discharge they showed no signs of any cardiac affection either valvular or muscular.

2. *Cases with Undoubted Organic Lesions.*—In this group there were 85 cases, or 32 per cent. In 95 per cent. of these the mitral orifice was involved and in 23 per cent. the aortic orifice. In 18 per cent. both the aortic and mitral orifices were involved. In the St. Thomas series out of 535 cases the mitral valve was involved in 97 per cent. and the aortic valve in 12 per cent. It is interesting to note that in our series the aortic valve was involved in practically double the relative number of cases in the St. Thomas series. One would be inclined to say from general impression that the reverse might have been expected because the writers on cardiac disease in Great Britain lay rather

more stress on rheumatic involvement of the aortic orifice than is usually done in this country. Of the 85 cases with organic valvular lesions mitral insufficiency was found in 54, mitral stenosis in 3 and mitral stenosis and insufficiency together in 8. This gives 76 per cent. of all cases with the mitral valve alone involved. Mitral insufficiency with aortic insufficiency occurred in 12; mitral insufficiency and aortic stenosis in 1; mitral stenosis and aortic insufficiency in 1. In 2 double lesions of both aortic and mitral orifices were thought to be present and in only 4 cases pure aortic insufficiency without mitral involvement. This gives a percentage of 4.7 for an aortic lesion alone. In the St. Thomas series the aortic orifice alone was involved in 3 per cent. It may be noted that so far as known no case of ulcerative endocarditis occurred in this series.

3. *Doubtful Cases.*—In this group are 78 cases, or 28 per cent. Of these 60 were discharged with a cardiac murmur present, the exact nature of which was doubtful. In 18 there was a murmur present at some time during the course of the disease, which disappeared and the patients were discharged with clear heart sounds. These latter cases are included with this doubtful group because it is impossible to say just how much involvement of the endocardium there had been. It may be said that practically the only sign of cardiac involvement in all the cases of this series was the murmur. The heart was not enlarged, its rate was normal, there was no thrill or any other sign suggesting cardiac disease. By far the largest division of these 60 cases is that in which the first sound was heard at the apex accompanied by a soft murmur, not carried to the axilla and not heard over the base of the heart, while the second pulmonic sound was not accentuated. There were 24 cases in this group. In 3 additional cases the only difference was an accentuated second pulmonic sound. In 3 others a reduplicated second pulmonic sound was present only on admission. In another group comprising 6 cases the first sound was heard at the apex accompanied by a soft systolic murmur heard out as far as the mid-axilla. In 8 cases there was a soft systolic murmur at the apex not carried to the axilla, but heard over the body and in the pulmonic area. In 5 cases the first sound was heard at the apex accompanied by a soft murmur not carried to the axilla and not heard over the body, but present in the pulmonic area. In 8 cases the first sound was clear at the apex, but there was a soft systolic murmur heard only in the pulmonic area. In 2 cases the first sound was clear at the apex, but there was a soft systolic murmur over the base. Of the 11 cases in which a murmur was heard at the base or in the pulmonic area only, one would be inclined to say that the murmur probably did not mean any definite cardiac involvement, and this especially in the cases where it altered with a change in position. In reference to the larger group of 49 cases, in which the principal feature was a soft systolic murmur heard at the apex, one has more difficulty in arriving at any sure conclusion. In many of them probably only time enables one to know with certainty. In some instances patients were discharged with a murmur thought to be only functional, but returned subsequently with undoubted signs of an organic lesion. Others, again, who went out with a suspicious condition returned with a normal heart and clear sounds. It may be noted that cases like those here described occurred in the group in which the murmurs appeared and disappeared under observation.

In the second division of this group are 18 cases in which there were murmurs which appeared and disappeared while the patient was under observation, the heart being otherwise perfectly negative. In 7 of these there was only a soft systolic murmur at the apex which was not carried to the axilla. This murmur persisted for periods varying from 2 to 14 days. In 1 case it was accompanied with pericarditis, in 1 other case with pericardial effusion. In 7 cases there was a soft systolic murmur at the apex, which was carried to the axilla and also heard in the pulmonic area or over the body. This murmur persisted for periods of 10 to 30 days. In 2 cases a soft systolic murmur was heard only in the pulmonic area, and in 1 only over the body of the heart.

The conditions that occur in the course of an acute rheumatism which may cause these murmurs are various. The most important are (1) fever, (2) toxemia, (3) anemia, (4) myocarditis, (5) dilatation and (6) endocarditis. The first two are probably often operative in the early stages of the disease and may have been a cause in some of the cases in which the murmur cleared up with the subsidence of the acute symptoms. But they hardly explain a murmur which persists, unless we believe that they may mean more or less permanent change, most probably in the heart muscle. Anemia may have been a factor in some instances, but was not a prominent one. The incidence of myocarditis is difficult to estimate. It would be impossible to give any positive symptoms and signs for minor grades of it. Yet the toxemia of acute rheumatism may affect the heart muscle more than we imagine. Dilatation of the heart stands in much the same relationship. It was possible to recognize its presence in some cases, but how frequently the lesser degrees occur would be impossible to state. Yet it may be taken for granted that few of the patients were discharged with any degree of dilatation, and hence while it may explain some cases of temporary murmur, it does not explain the cases with more or less permanent murmur. Endocarditis is probably the most important factor in the production of these murmurs. How extensive this process may be in such cases we are unable to say, but it is quite possible that in many of this group there were small vegetations near the margins of the mitral segments. Such may be associated with but little actual regurgitation of blood and be of but little immediate importance. These vegetations may be gradually absorbed until only smooth elevations remain. How far such cases may undergo a gradual progressive change in the valves, with subsequent marked regurgitation, without any definite further rheumatic infection, is a question. But we must remember the tendency to slow progressive sclerotic changes under any circumstances. It would seem reasonable to suppose that in any event a subsequent attack of rheumatism would find such valves more readily affected. When we remember that in some cases with undoubted acute endocarditis a murmur may only appear late or not at all, the difficulties in the exact diagnosis of endocarditis are evident. The symptoms and physical signs may be very variable and uncertain. These murmurs are probably akin to those transitory ones noted in chorea. A positive verdict as to the exact nature of many of them can only be reached by time. Yet in general terms it would seem reasonable to suppose that in many of these cases the slowly advancing process leading to definite change in the mitral valves has begun, and that years later such patients come again under observation with the undoubted signs of organic mitral disease.

The question of the treatment of these cases is an important one. How long should such a patient be kept

in bed and at rest? Certainly until as many as possible of the etiologic factors noted before can be excluded. It is in our power to do this usually in the case of fever, toxemia, anemia and dilatation, but in a less degree with myocarditis. As to endocarditis we can speak with little certainty. The only safe rule is to consider them all as possible cases of this condition. We have treated these cases much after the method so strongly advised by Caton.[3] The first essential is, of course, prolonged, complete rest. How difficult this is in private practice and how often impossible in hospital work we all know. The average hospital patient will rarely consent to remain at rest after the acute symptoms have subsided. With children it is not easily done. The second is the application of small blisters over the precordia. We believe this to be often of considerable value in all the cardiac complications of rheumatism. The third is the administration of sodium or potassium iodid in small doses for some time.

It may be said in reference to the present series that of the 85 cases with definite organic disease on discharge, in 5 this developed under observation. In the remainder the murmurs were present on admission. Of these 5 cases in 3 the attack was the first, in one the second and one had numerous attacks in childhood, but had been free for 23 years before the present attack. All these patients were over 20 years of age. Of the 60 cases with a doubtful murmur on discharge, in 4 this came on under observation, 3 being in the first attack and one in the second.

To sum up, it seems reasonable to suppose that in many of the cases classed as "doubtful" there had been some changes in the mitral valves likely to be progressive. Such patients years later will probably be found to have organic lesions.

Murmurs Which Developed Under Observation and Which Persisted.—There were 9 cases in this group. Of these 5 were regarded as cases of definite organic lesion, all being mitral insufficiency. Two of these came on within a period of 24 hours; that is, from perfectly clear heart sounds a murmur developed in one day which was permanent. In one case the first change noted was reduplication of the second sound in the pulmonic area. In a few hours this was followed by murmurish quality of the first sound at the apex, which rapidly became a positive murmur. In the other case within a few hours the transition was noted from a clear first sound to a murmurish quality and very soon a definite murmur. It is worthy of note that in all these cases the pulse was not affected in any way that could be made out at the time of development of the murmur. It was little above normal in any of them. The remaining four of these nine cases were doubtful and are included in the third group given before.

The influence of the age of the patient at the time of the first attack is a well-known factor in the development of endocarditis. The comparison of the ratios of the cardiac conditions is given for two periods, below and over the age of 20 years. The large percentage of doubtful cases is to be regretted, but there seems no other way of disposing of them:

Age at First Attack.	Heart Clear.	Organic Lesion.	Doubtful.
Below 20 years....	33.6%	44.5%	21.8%
Above 20 years....	50	21	29

The comparison is striking, and the nearly double percentage of the cases with organic lesion in those with the first attack below 20 years is to be noted.

If the cases be arranged by decades the high percentage of cases with organic lesion in those coming within the first ten years is very marked. The figures give the percentages:

Age at First Attack.	Heart Clear.	Organic Lesion.	Doubtful.
1-10	18	64	18
11-20	37	40	23
21-30	46	18	36
31-40	41	12	47
41-50	60	24	16
51-70	25	37	38

Pericarditis.—This occurred in 16 cases, or 5.9 per cent. These figures agree fairly closely with those of the St. Thomas series, namely, 6.1 per cent., and the figures from the St. Bartholomew series, namely, 7.5 per cent. These percentages are very much lower than those given by the older writers on the disease, the most common explanation given for the diminished frequency being that it is due to the use of salicylates. The age of the patients with pericarditis varied from 12 to 51 years, 6 were below the age of 20 years and 10 over it. Contrary to the experience of many writers, relatively few cases, only 3, occurred with the first attack, 7 occurred with the second attack and 5 with the third. As to the time of onset of the pericarditis the earliest was on the fifth day, the patient being admitted with the pericardial rub present. The latest time of onset in the disease was on the 61st day in one case. All but two were within the first four weeks. There was one case with pericardial effusion present on admission. The duration of the pericardial rub was very variable. The shortest period was five days, when effusion occurred. The longest period was 18 days, observed in two patients. Delirium occurred with pericarditis in only one case. This is rather surprising, considering the emphasis which is usually laid on the association of the two conditions. The temperature did not go above 102 in 9 of the patients, in 2 being below 101. In 3 it was irregular, not going above 103, in 2 not above 104, and in only 1 reached 104.5. The pulse rate was below 100 in 2 cases, went up to 115 in 4, up to 125 in 5, and from 136 to 140 in 4. Leucocytosis was present in the 7 cases where a count was made. In the majority the number varied between 15,000 and 19,000 per c.mm. The highest count was 35,000 per c.mm.

It is probable that in the majority of these cases there was some involvement of the myocardium. This, however, may be difficult to estimate. In cases with definitely associated pericarditis and endocarditis, the myocardium is probably always involved. Among these 16 cases there seemed undoubted associated endocarditis in 8, in 4 there was doubtful evidence of it, and in 4 no evidence of endocardial disease. As already noted, it may be impossible to accurately estimate the amount of involvement of the heart muscle.

Results.—Effusion occurred in 2 cases, in 1 of which it was present on admission. The pericardium was tapped in one of these with some temporary relief, but death occurred later. Adherent pericardium, of the presence of which there could be no doubt, was present in 3 cases. Death followed in 3, in 1 with effusion, in all with endocarditis, and, of course, probably with myocarditis as well.

Adherent Pericardium.—This was found to be present in 6 cases, in 3 of which it apparently followed pericarditis, which occurred under observation. None of the patients with adherent pericardium were admitted in the first attack, 3 of them being in the second attack and 1 each in the third, fourth and sixth. In one patient, who was continuously under observation, a period of four months elapsed between the pericardial rub and undoubted signs of adherent pericardium.

3. Caton: British Medical Journal, Oct. 12, 1901.

Pulse.—The general impression on going over the figures of the pulse rate is one of surprise that the average is not higher. In 59 per cent. of the cases the pulse rate never rose above 100. In only 3 cases was it above 130, and in only 14, or 6 per cent., was it over 120. More than half of these were cases of pericarditis. When one considers the fever, the toxemia and the not infrequent endocardial and myocardial involvement it is certainly surprising that the pulse rate is not more increased than these figures indicate. As has been noted, we have observed cases with endocarditis and the development of definite organic lesions in which the pulse rate was practically unchanged. It is important to remember this and not attach much importance in a doubtful case to the absence of any disturbance of the pulse as being against endocarditis. Yet the contrary may be true, as in one patient who, during recovery in his first admission, had a persistently rapid pulse, about 120. His heart was negative and the sounds were clear. Five days after discharge his symptoms returned and he was admitted with arthritis and a soft systolic murmur at the apex, which persisted without any other signs of cardiac disease. On discharge this murmur was very soft and the pulse was 100. There may have been endocarditis throughout without any cardiac signs at first or the rapidity may have been due to myocarditis.

Urine.—This was apparently clear throughout in 130 cases, or 48 per cent. Albumin was found only on admission or once subsequently in 96 cases, or 34 per cent. Of these cases casts were found in 18, while no casts were discovered in 78. Albumin was found occasionally, but was not constant in 14 cases, or 5 per cent. Casts were present in 6 of these, and in 8 none were found. Albumin was present throughout in 31 cases, or 11 per cent. In 22 of these casts were found, in 9 no casts. It has to be remembered in connection with the finding of casts that in the great majority the urine was alkaline in reaction. The diazo-reaction was positive in 3 out of 91 cases where it was looked for. Bile was found in 2 cases and sugar in 2 cases. Quantitative uric acid estimations were made in some cases without any special departure from normal being found.

Blood.—The average hemoglobin percentage in 77 cases was 65.9 per cent. The average count of the red corpuscles in 69 cases was 4,532,000. These counts were, as a rule, taken when the patient came under observation. Later counts give rather lower counts in some cases, but the drop is not as marked as might be expected. The most marked drop in hemoglobin percentage was of 20 per cent. in twelve days, but with this the number of red cells was practically unchanged. As soon as possible the majority of the patients are put on iron, which may have some influence in diminishing the reduction. The anemic patients are probably better put on iron from the beginning. The average leucocyte count in 83 cases was 11,776. Of these, however, in 29 the count was below 10,000, and taking the average of the remaining 54 cases the count is found to be 14,260 per c.mm. This represents the total of the average count of the leucocytes in these cases, but if the highest leucocyte count in each case be taken the average for the whole is 15,380 per c.mm. In 17 cases the count was over 15,000, and in 4 over 20,000. The highest count obtained in any case was 38,000. A full differential count was made in 11 cases. These were practically all normal and the average count was polymorphonuclears 76 per cent., small mononuclears 13 per cent., large mononuclears and transitionals 8 per cent., eosinophiles 2 per cent., Mastzellen less than 1 per cent. It may be noted that leucocytosis occurred in all the cases of pericarditis where a count was made, but that many of the undoubted cases of endocarditis had normal counts. No constant connection could be traced between endocarditis and leucocytosis.

Miscellaneous Symptoms.—While the patients were under observation there was a variety of rarer symptoms, some of which may be noted. Tonsillitis occurred in 10 cases, chills or chilly sensations in 14, erythema in 8, urticaria in 2, a bullous eruption in 1 and herpes in 6 cases. Delirium was noted in 5, in 4 of which it occurred with the administration of the salicylate and was thought to be due to that. Chorea occurred in 4 instances at the same time as the rheumatism. Severe abdominal pain occurred twice without any evident cause. Both the patients recovered. In one there was marked leucocytosis. One may possibly ask if the severe abdominal pain in rheumatism is comparable to that sometimes seen in gout, as in a case reported at this meeting by Dr. Futcher. Double parotitis occurred in 1 case with recovery. There was some swelling of the tonsils. The condition of the heart was doubtful and it was impossible to say that there was endocarditis. The possible etiology of the parotitis is interesting in comparison, for example, with the same complication in pneumonia where an endocarditis is usually stated to be present. Iritis in one eye occurred in only one instance.

Subcutaneous Fibroid Nodules.—These were found in 4 cases, or 1.5 per cent. It is interesting to note that in the series from St. Thomas' Hospital only 9 instances were found in 997 cases, which is slightly under 1 per cent. Comparison between the figures of the two hospitals does not warrant any definite conclusion, but it is certainly surprising to find that these nodules apparently occurred as frequently in our experience as in one of the London hospitals, and this despite the fact that we have comparatively few children admitted to the wards. At St. Bartholomew's, during a period of six years for which records could be found, there were 16 instances among 662 cases, which gives a percentage of 2.4.

Nervous Complications.—Delirium occurred in 5 cases, in 4 of which apparently with the administration of salicylates, and in the remaining case with pericarditis. It was not due to high temperature in any case. It was in all active in character. Coma and convulsions did not occur. Chorea was associated with the attack of rheumatism in 4 cases. These were all children aged 14, 12, 8 and 6 years. In the first two there was definite endocarditis, and while the latter two are included in the group of "doubtful" cardiac cases, it is probable that they also had endocardial involvement. Only one had chorea previously. There was only one patient who showed symptoms of meningitis. This was a boy aged 12, who was admitted in his first attack. His mind was clear. There was marked rigidity of the neck muscles and the chin could not be brought near the sternum. There was no marked retraction and Kernig's sign was not typically present, although a suggestion of it was noted on both sides. The condition persisting, lumbar puncture was done and 40 c.c. of clear fluid obtained. Cultures from this were negative. The condition persisted for nearly two weeks. A second lumbar puncture gave 15 c.c. of clear fluid. During this time the leucocytes varied from 14,500 to 36,000 per c.mm. There was irregular fever varying from 99 to 105. He recovered after a protracted attack.

Pulmonary Complications.—These were comparatively few in number. In a number of cases some dulness was noted, usually at a base, and with this some blowing

breath sounds, but no tubular breathing. This occurred in several of the cases with pericarditis. Of true lobar pneumonia apparently only one case is recorded. In this the pneumonia was double and associated with both endocarditis and pericarditis. One patient was just convalescent from pneumonia when the attack of rheumatism began. Pleurisy was not of common occurrence. In the 16 cases with pericarditis it was present only in 3, while a pleuro-pericardial rub was heard in 3 others. Severe bronchitis occurred once, and also pulmonary hemorrhage with pulmonary tuberculosis in one case.

Duration.—The average stay of the patients in the hospital for the whole series was 26.4 days. The average duration of the attack for the whole series was 38 days, which rather supports the idea that "six weeks" is one of the essential points in the treatment of acute rheumatism. This, of course, is longer than the average stay in the hospital, as many had been ill for some time before admission, often without treatment.

Relapses.—It is difficult to say definitely what constitutes a relapse in acute rheumatism. If by a relapse we mean a return of the symptoms after a period during which they were completely absent, there were 12 cases in this series, or 4.4 per cent. But if the term is applied to cases in which the symptoms partially subside, to be followed by a period of recrudescence or exacerbation, it is most difficult to estimate the number. There were many prolonged cases with exacerbations, and it would be very hard to know where to draw the line, which to call relapses and which recrudescences.

Cultures.—It is disappointing to report that our results throughout were practically negative, cultures from the joints, the blood and the urine yielding nothing positive. Cocci were grown in cultures from the tonsils. In one case the colon bacillus was obtained from the urine. The results have some negative value, especially in reference to the absence of streptococci and staphylococci from the cultures. All cultures made in the line of the work of Achalme were quite negative.

TREATMENT.

This will be referred to very briefly. The patients, of course, are kept absolutely at rest, are usually put on a milk diet and given large quantities of water, preferably alkaline. They wear flannel and are between blankets. The usual custom is to give the sodium salicylate in doses of 15 grains every two or four hours for one or two days or until the pain is relieved. Then oil of wintergreen in doses of 15 drops four times a day is usually substituted. With this the potassium salts are given in doses sufficiently large to render the urine alkaline. The local treatment of the joints usually consist in the application either of lead and opium lotion or of the oil of wintergreen. The latter we have found especially helpful. Fixation of the joint was frequently employed. Special conditions receive indicated treatment. Pain was the most frequent of these. One of the coal-tar products or morphia was most often used for this. The majority of the patients are put on iron at some period of the treatment. The special treatment of the cardiac cases has been referred to before.

DIAGNOSIS.

It is instructive to note the conditions which we have most often mistaken for acute rheumatism. This mistake we should say is much more frequently made than the error of taking rheumatism to be something else. Of polyarticular conditions gout has been the most difficult disease to distinguish. In four cases which afterwards were proved to be gout we mistook the polyarticular manifestations for those of acute rheumatism. This is a mistake, the possibility of which has probably not been sufficiently impressed on the profession of this country as most of us regard gout as being relatively infrequent and forget that the acute polyarticular form may be very difficult to distinguish from acute rheumatism. The age, sex, occupation and habits of the patient are all important in making a diagnosis of gout. In the absence of tophi, probably the systematic examination of the urine will be of much assistance.

The acute form of arthritis deformans may be often a cause of difficulty in diagnosis. Several instances of arthritis deformans were admitted to the hospital with the diagnosis of acute rheumatism. Here, as is well known, the differential diagnosis may be most difficult. Probably changes in the joints, especially the small joints, which are very apt to remain after the acuteness of the attack of arthritis deformans is over, are one of the best aids in making a diagnosis. The previous history and the presence of other suggestive signs of arthritis deformans are sometimes of help. The multiple gonorrheal arthritis, of course, frequently offers difficulties in recognition. All cases with atypical features are always carefully examined with the possibility of gonorrheal origin in mind. It is well to have a suspicious attitude of mind toward all cases of doubtful arthritis. We have regarded several cases as acute rheumatism which were afterwards proved to be gonorrheal arthritis. One case is of rather especial interest. It was that of a woman who was near the full term of pregnancy. She was admitted to the medical wards with a multiple arthritis which we thought was rheumatic. Before delivery she was transferred to the maternity ward, and after the birth of the child cultures made from the uterus yielded gonococci. The various forms of septic arthritis probably give most difficulty in children.

Of the monarticular conditions the gonorrheal arthritis may give difficulty, but the mistake most often made was in distinguishing between the rheumatic and acute tuberculous joint. The tendency was rather to regard monarticular rheumatic joints as tuberculous than the contrary. In a recent case in which the only joint involved was the hip, all the ordinary signs of tuberculous involvement of that joint were present. We regarded the case as one of tuberculosis until with the appearance of subcutaneous fibroid nodules there were symptoms in the other joints. The patient subsequently came under observation with a second well-marked attack of acute rheumatism. The monarticular form of arthritis deformans is rarely likely to lead to error.

MORTALITY.

Of the 270 cases only 3 died in the hospital, which equals 1.1 per cent. The St. Thomas series gave exactly the same rate, and that from St. Bartholomew's 2.2 per cent. All the fatal cases had endocarditis and pericarditis, or one might better say carditis. One died on the 13th day of the disease, the second on the 30th day with aortic and mitral endocarditis and pericarditis with effusion, and the third on the 37th day with aortic and mitral endocarditis and pericarditis. All were in the second attack.

This figure—1.1 per cent.—is small, but it does not represent the actual mortality from the disease. Of many of this series it may be said that the end is not yet. Most diseases are given their full due in the mortality returns, but acute rheumatism is an exception. The books would have to be kept open too long, and it might be 1910, 1920 or 1930 before the returns of the acute rheumatism of 1901 could be completed.

THE SALICYLATES IN ACUTE RHEUMATISM.*

JAMES J. WALSH, M.D., PH.D.
NEW YORK CITY.

It is generally conceded that the salicylates in some form constitute the most satisfactory remedy for acute rheumatism. These drugs are no longer considered a specific for rheumatism in the sense that quinin is a specific for malaria, but they have some very definite action with regard to the general symptom-complex known as acute articular rheumatism that makes the patient more comfortable than any other set of remedies. It is even allowable, in a certain sense, to use the expression that the employment of salicylates constitutes a therapeutic test for true rheumatism. The salicylates do not affect secondary infectious complications of joint structures, due either to the pus cocci, or to the influenza bacillus, or to the microbe of mumps or other such affections, nor to the arthritis that is due to the gonococcus. It is true they do not affect all cases of rheumatism favorably. But there is very good reason to suspect rheumatic cases that are uninfluenced by the salicylates to be dependent on some other etiology than that of simple acute rheumatism.

DOSAGE OF THE SALICYLATES.

All those who consider that the salicylates have a use in rheumatism are agreed that they must be employed in large doses. No matter in what form the salicylates are employed, from 90 to 120 grains per day must be administered during the continuance of the acute symptoms. There are many patients with an idiosyncrasy for the salicylates who can not stand this amount of the drug. Certain nervous individuals develop distinct neurotic symptoms that may even proceed to the extent of delirium. In acute rheumatism without hyperpyrexia, if delirium develops at a time when the patient is being given salicylates freely, the first rule must always be to stop the salicylates and note the result. Almost invariably the delirium will subside. The salicylates are not well borne by many stomachs. This might seem an unimportant element in the case, since rheumatism must be brought under control and the disturbance of normal digestion for a week might appear a trifle. Rheumatism is, however, one of the severest of the infectious diseases in its effect on the blood. A rapidly developing and severe anemia is a constant concomitant. Disturbance of digestion will further add to this important symptom and so make the case much more liable to serious sequelæ.

CONTRAINDICATIONS TO THE SALICYLATES.

Besides the nervous and digestive symptoms already mentioned, there is at least one other extremely important contraindications to the use of the salicylates. The derivatives of the salicylates in the system are distinctly irritant to the kidneys and yet they are all eliminated by these organs. If there is nephritic trouble present this will almost surely be rendered worse by the irritative conditions set up because of the presence of the salicylic derivatives. This will react to increase the anemia and make heart complications more serious. As a rule, then, the first thing to do in nephritis is to examine the urine carefully for any signs of nephritis. When it is present it seems advisable to exclude the salicylates from the list of remedies to be employed. If taken in amounts that are not sufficient to produce marked irritation of the kidneys they do no good to the rheumatic process. It is to be remembered after all that they are symptomatic remedies and not specifics. Whenever in the course of rheumatism signs of kidney irritation develop with considerable albuminuria, besides casts and smoky urine, then it seems better to substitute some other sedative drug for the salicylates.

Young persons particularly are liable to suffer from nervous symptoms because of the administration of salicylates. Young girls quite often develop a delirious condition, which does not of itself, however, constitute a contraindication to the further continuance of the salicylate treatment unless it should become very severe and make the patient so restless as to endanger the spread of the disease because of the movement of affected limbs.

There may be in certain cases the development of salicylic dyspnea. This state is characterized by rapid though deep breathing. It is often a source of worry to the patient's friends, and while not of itself an absolute contraindication, if persistent, or if the breathing becomes very rapid, it must lead to the substitution of some other remedy.

FORMS OF SALICYLATES.

Salicylic acid was the original form of the drug employed in the treatment of rheumatism, and gave excellent results. It proved, however, rather irritating for many stomachs, and so other forms of the salicylates came to be employed. The salicylate of sodium is perhaps the most used form in which these remedies are now administered. There are many, however, who still employ the original salicylic acid and obtain more satisfaction than with any other preparation. Strümpell suggests the use of sodium salicylate whenever the primary symptoms are very acute and an immediate effect is desired, because this drug can be given in large quantities, a dram, or even more, at a dose. He suggests in addition, however, that the alternation of sodium salicylate and salicylic acid will sometimes give more satisfaction than either of these drugs alone.

In England salicin is rather popular and is said to disturb the stomach less and also to be less irritative for the nervous system. It should not be forgotten that some form of extract of willow—a remedy containing the principles of the salicylates—has been in use in England for a century. Salicin must be used in somewhat larger doses than salicylic acid or sodium salicylate. Many other forms of salicylates have been suggested. Kinnicut has obtained excellent results without the usual annoyance from oil of wintergreen. Certain of the other salts of the salicylic acid are employed. Each of them is for a limited number of clinicians the best possible form for the administration of these remedies. The state of affairs in this respect reminds one very much of the similar claims with regard to various compounds of bromid that are used for epilepsy. It is the bromid itself, however, that does good and that has to be employed despite the inconveniences attached to it, and the same thing is true with regard to the salicylates, and it would seem to be only by accident or individual idiosyncrasy that a special preparation seems to prove any better than the other.

There are three forms of salicylic acid that may be obtained for remedial purposes. One is confessedly a synthetic product, a second is derived from synthetic oil of wintergreen and may therefore also be considered a synthetic product, and the third is derived from genuine oil of wintergreen. There are good therapeutic authorities who insist that the difference of reaction of

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. Frank A. Jones, George Dock and J. M. Anders.

these three forms of the acid is in certain persons very marked. The synthetic products are not well borne at all by the stomach, prove more irritating to the kidneys and as at times a sufficient amount of the drug can not be taken under these circumstances, they may fail to affect the symptoms. This is a matter of clinical observation that each one must decide for himself, but the criticisms are sufficiently numerous and authoritative to make it clear beyond a doubt that the subject is well worthy of consideration.

METHOD OF ADMINISTRATION.

With regard to the time at which the salicylates should be given there is some variance of opinion. There is no doubt that in accordance with the daily rhythm of temperature the temperature of rheumatic patients is higher in the afternoon and evening and they are almost sure to be more uncomfortable and to present more symptoms of the affection at this time.

It has been suggested, then, that the salicylates in whatever form they are given should be administered so that the daily dose is given before 4 o'clock in the afternoon. The patients then usually pass a quiet night, or, if necessary, may be given some opium and most of the symptoms of salicylism will have begun to remit before further doses of the drug need be given the following morning. Strümpell says that when called in the evening he always administers a dram to a dram and a half of the salicylate of soda, so that the patient may not be disturbed during the night and may be left at rest as much as possible. The following day he usually uses salicylic acid in divided doses of fifteen grains every two or three hours.

THE SALICYLATES AND HEART COMPLICATIONS.

When the salicylates were first introduced, their prompt results in the relief of pain and reduction of fever raised great hopes of their effectiveness, also in introducing the number of heart complications from rheumatism. These hopes were sadly disappointed. Careful collation of statistics by Professor Pribram in his book on acute rheumatism in the Nothnagel series shows that at least there are no fewer heart complications from rheumatism since the introduction of the salicylates, and the statistics seem even to show that heart complications are a little more frequent. English statistics particularly appear to justify the conclusion that the use of the salicylates by relieving the pain and so tempting patients to movement sooner than is proper for them has actually led to more serious heart complications than before. There are a number of the older clinicians who insist that they saw fewer heart complications under the old alkali treatment for rheumatism. It seems advisable, then, that alkalies should always be used in conjunction with the salicylates. Sufficient of the alkalies must be employed to render the urine alkaline. They are not employed with any thought of the presence in the blood either of uric acid or lactic acid, but entirely on clinical grounds.

THE SALICYLATES AND THE RHEUMATIC PROCESS.

There is no doubt that the salicylates relieve the pain, lessen the fever, diminish the restlessness and so make the patient very comfortable. There is considerable doubt, however, as to whether the remedy affects the rheumatic process itself. There are some therapeutists who believe that the salicylic acid acts as an antiseptic in the system and so is directly curative of the rheumatism, because it makes the tissues an unsuitable place for the further growth of the organism which now admittedly causes rheumatism. Unfortunately for this theory a careful study of the records of hospital cases treated with or without the salicylates shows that the disease is not shortened by the administration of the salicylates and that it is only the patient's comfort that is consulted. There are even those who say that the relief of the pains in the joints tempts patients to use their limbs somewhat and by disturbing Nature's reactive and protective mechanism favors the development of heart complications. Old practitioners insist, however, that they no longer see the very severe cases of rheumatism that were quite common in the early days of their practice thirty and forty years ago. Then it was not unusual to have patients lie in agony for days and even weeks with high fever and intense restlessness with no possible means of affording relief.

Hyperpyrexia is one of the complications that is undoubtedly much less frequent in acute rheumatism than before the introduction of the salicylates. This constitutes one of the most serious immediate complications of the disease. The mortality from acute rheumatism is not very high, but a considerable proportion of it is due to hyperpyrexia. In recent years Strümpell says, and Eichhorst agrees with him, that he has seen hyperpyrexia very rarely, and then only in cases where the salicylates were not used or where an insufficient amount of these remedies was employed.

SUBSTITUTES FOR THE SALICYLATES.

The salicylates are not a specific for rheumatism and the beneficial effects obtained from them may also be derived from cognate coal-tar products. Antipyrin has been very extensively used in Germany for this purpose. It was, for a time at least, and is, I believe, yet the routine drug employed in the first medical clinic of the Charité Hospital of Berlin. This is under Professor von Leyden's direction, which is of itself a guarantee that the treatment is thoroughly conservative. Like the salicylates, antipyrin must be used in large doses. From sixty to ninety grains per day are employed for three or four or more days, until the painful symptoms of the rheumatic condition have subsided. With our prejudices against antipyrin in this country this dosage seems enormous. No bad results have been noted, however, and it seems to be well understood now that when antipyrin is badly borne it is not due to any special toxic quality of the drug, but to an idiosyncrasy in the patient. Phenacetin in similar doses to those already mentioned for antipyrin has also been employed with good results. Either of these drugs may prove effective when the salicylates fail. If the salicylates are going to do good, decided improvement will be noted on the second or third day. If pain continues after this time one of these substitutes should be employed.

Investigations of New Remedies.—The London *Lancet* says: Our experience proves that it is becoming almost impossible to admit articles in the columns of the *Lancet* from the pens of general practitioners and others dealing with the results of their therapeutical investigations into the value of new preparations because all the favorable passages will at once be pounced upon by the enterprising purveyor, perhaps garbled, almost certainly dissociated from their context, and scattered broadcast over the land. We are thus, perhaps, prevented, and by the very people who would profit by the publicity, from putting before our readers papers the practical value of which may be great. The public, the medical profession, and the purveyors alike suffer. The only way to remedy the position is not a satisfactory one, but it is one to which we must have recourse.

TYPHOID FEVER IN AN INFANT UNDER ONE YEAR OF AGE.*

E. F. BRUSH, M.D.
MT. VERNON, N. Y.

In this age of serotherapy and prophylaxis the question of immunity is one of prominence. Typhoid is a prevalent and constant disease. Its causation and its avenues of attack are comparatively well known. No one to-day disputes the fact that a characteristic bacillus most commonly water borne and cultivated in the intestinal canal is the prime cause, but there has been a question in the literature of typhoid regarding the immunity of infants under one year old.

Previous to 1840 infantile intermittent fever was a commonly described disease with nurslings. About this time, 1840, Rilliat and Taupan each independently published articles to show that what was previously described as infantile intermittent fever was in truth typhoid fever. I have not been able to discover exactly on what Rilliat and Taupan based their deductions.

We find, however, in 1847, Condie, in his book, "Diseases of Children," saying: "It is more than probable that typhoid will be found to be a much more frequent disease among children than has heretofore been supposed. The memoirs of Rilliat and Taupan afford sufficient evidence that many of the cases of what was formerly considered as enteritis in children, as well as of that form of fever which has been vaguely denominated worm or gastric, are in fact cases of genuine typhoid fever."

Condie also quotes the "Vital Statistics of Philadelphia from 1835 to 1845," which gives four cases of typhoid fever in children under one year of age out of a total of 57 cases. Still Condie does not say that he himself ever saw a case of infantile typhoid.

Charles West, in his lectures on "Diseases of Infants and Children," in 1850, quoting Rilliat and Barthaz, says that "the postmortem evidence in what was formerly called remittent fever you will find enlargement, tumefaction and ulceration of Peyer's glands." Nor does West say that he himself had seen a case of infantile typhoid.

In 1864 Murchison exhibited at the London Pathological Society the intestines of an infant six months old who had been attacked with typhoid fever at the same time with her mother. This I find quoted in Keating's Cyclopedia of the Diseases of Children. Wilson, who wrote the article in the cyclopedia, says that cases in the first year of life are exceedingly rare, and, quoting Murchison, also affirms, basing his statements on the reports of Rilliat and Taupan, "that previous to 1840 the opinion was universally held that infants enjoyed an immunity from typhoid." Excepting that Rilliat and Taupan may have had some cases this of Murchison is the first case that I can find on record.

Austin Flint, in 1868, says that typhoid fever occurs but rarely in infants, and he quotes Murchison's case. There is no evidence that he himself had ever seen a case.

Steiner, who had been physician to Francis-Joseph Hospital for Children for fifteen years, in his interesting and useful compendium on "Diseases of Children," published in 1871, states that there had been 1,180 cases of typhoid fever in the hospital, but that this disease is not commonly seen in very early life, though some observers, Bedanar, Buhl and Loschner have recorded its occurrence in children a few weeks, or even a few days old. But Steiner does not report that he himself had ever witnessed a case in an infant.

I find in the *British Medical Journal* of April 19, 1902, a report of enteric fever in an infant four months old. It was nursed by a mother who also had typhoid; the child died; and J. R. Lowe, L. R. C. P. & S. Edinburgh, adds to this report: "This case is of interest because on looking up the literature on the subject I find there have only been two recorded cases of enteric fever in infants under one year old."

W. G. Thompson, in his text-book of "Practical Medicine," 1900, says: "The fever is very rare earlier than the second year, and from its etiology its occurrence is impossible in a breast-fed infant." Thompson says that he saw, at the Presbyterian Hospital, in 1896, an undoubted case in an infant nine months old, but he fails to state whether or not the infant was nursing.

So it may be readily seen that typhoid fever is an extremely rare disease in infants under one year of age. Murchison's case is quoted everywhere, also Rilliat and his compeers are quoted by nearly all the compilers. Therefore, I will be excused for bringing before this Section a case which I saw and reported in mass with the rest of an epidemic occurring in the backwoods of Maine. Briefly stated, my case occurred in a family of nine persons, two adults and seven children, domiciled in a log house with two rooms. There were four other families in the settlement, but there was considerable distance between the houses. They were completely isolated; there was neither store, church, school, physician or privy in the entire hamlet. No one had visited this family from April, when the first case occurred, until October, when the writer saw them. There was no medication. The only food in the house was flour, pork and beans. The source of contagion was from a polluted spring. The mother was nursing an infant six months old when she herself was attacked in August. She continued to nurse the baby until her milk dried up by the fever, about one week, then the baby was put on a diet of flour paste. This was made with the water from the polluted spring, and the child also drank the polluted water. About the first of October the baby sickened. When I first saw her she had been sick ten days, and was doing fairly well, and I believed she recovered, because I left an addressed envelope with the parents to send me word if anything serious happened, and I have not heard from them. In this case it will be seen that the baby used the polluted water for nearly three months before she sickened. The mother had used the water nearly four months before she was attacked, but two other members of the family did not sicken until September, and therefore had been using the water for six months previous to their attack.

Here was a nursling, under one year of age, who, though living in the same house where there was some one sick with typhoid fever from April until the middle of August, had been nursed by a fever-stricken mother, escaped until exposed to the same conditions as the other members of the family, then took the disease.

"One swallow does not make a summer," but one can not often find just the conditions that exist in this humble house where all the inmates when exposed to the same danger all alike, nursing mother and infant, took the disease. This is one instance showing that the infant did not resist typhoid contagion when the conditions were the same as with the adult members of the family.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. H. M. McClanahan, Edwin Rosenthal and Samuel W. Kelley.

DISCUSSION.

DR. A. C. COTTON, Chicago—I do not know of any subject that has appeared on our program for discussion during the past few years, aside from feeding and nutrition, that presents more interest to-day than typhoid fever among children and infants. It is only a few years since some of our best observers questioned the possibility of typhoid fever in infants under two years of age. It can not be more than eight or nine years since Dr. Charles Warrington Earle, Chicago, read a paper, reporting 13 cases of typhoid fever occurring in infants and children. This caused considerable discussion, and the general opinion seemed to be against the diagnosis made by Dr. Earle. No less an authority than Dr. W. P. Northrup, New York, basing his experience on a large number of autopsies in the New York Foundling Hospital, said that he had never met the postmortem lesions of typhoid fever there, though many diagnoses of typhoid fever had been made in that institution at the bedside. Clinical evidence has been frequently presented in favor of typhoid at all ages, but they have been apparently met by the statement that lesions were not found postmortem. Within a very few years a number of papers, presenting in the aggregate a large number of cases of unmistakable typhoid in infants and children, have appeared. We are all familiar with the able paper by Dr. J. Lovett Morse, Boston, and two papers have been presented by members of this section, Dr. J. P. Crozer Griffith, Philadelphia, and Dr. I. A. Abt, Chicago. These show that with proper clinical tests we can not escape the positive diagnosis of typhoid. This brings up the question as to why errors in diagnosis have been made in the past. The fact is that infants and children do not show the pathognomonic intestinal lesions formerly considered necessary for the diagnosis of enteric fever. We also know that the clinical history of the cases in children differs from that in adults. The Widal test is the only absolute test to-day, and it seems to be very generally accepted. That children react as readily as adults to this test I believe is also generally accepted. The type in children is no more widely different from the adult type than was the typical American typhoid different from the typical German typhoid fifteen years ago. I remember listening to an interesting discussion at that time of notable authorities at the New York Academy of Medicine. At that time they were only just willing to admit that typhoid fever could occur along with constipation because the old German description insisted on the necessity for the occurrence of diarrhea in cases of typhoid fever.

DR. J. P. CROZER GRIFFITH, Philadelphia—I believe thoroughly that this disease is much more frequent in early life than most of us think. In regard to the statement one often reads that in 2,000 autopsies at the New York Foundling Asylum the lesions of typhoid fever were found in no instance, it is to be noted that the same writer in another place stated that the lesions of the disease in infancy could not be distinguished from those of enterocolitis. The conclusion from those statements would be perfectly legitimate that all the enterocolitis cases were really instances of typhoid fever! The force of the first statement is destroyed by the second.

In the adult when there is continued fever we suspect typhoid fever, whereas in the child continued fever often leads to the suspicion that the child is "teething," or has indigestion. The possibility of the presence of typhoid seems to be forgotten. I have within a few weeks had a case of the disease in an infant in which the true diagnosis was hardly suspected until a Widal test was made and was found to be positive. I then found that the mother of this baby was sick with typhoid fever in another part of the hospital.

In a recent investigation by Dr. Maurice Ostheimer and myself 418 cases of typhoid fever were collected from medical literature and from our own experience, occurring in children of 2½ years and under. Twenty of those cases were born with typhoid fever. There were about 180 cases of typhoid fever in the first year of life. The greater number occurred in the second year, and a smaller number from 2 to 2½ years. I do not think, therefore, that we can truthfully say that this is a rare disease in early life. We may say that, as compared with the frequency in adult life, it is uncommon, but it is only relatively uncommon. I have seen typhoid fever at the age of 3 months, and at 7 months, and the case just referred to was 9 months old. The case occurring at 7 months I did not recognize until death occurred. That is the trouble—the diagnosis is often exceedingly difficult, even if we are alive to the possibility of the presence of the affection.

DR. ROSA ENGELMANN, Chicago—Dr. Rotch told us recently that the Widal reaction was often not positive in children before the fourteenth day, but I think it can be usually made available earlier. I have been in the habit of making it as early as the third day. In one case it was negative on the third day, and positive on the fifth day. I teach now that the Widal test is one of the means of making the diagnosis in typhoid fever in children especially.

DR. H. L. K. SHAW, Albany, N. Y.—I agree most heartily with Drs. Cotton and Griffith as to the frequency of typhoid fever in infancy. I heard Dr. Northrup read a paper some years ago in which he stated that he had never seen a case in a child under three years, and made the same statement about the autopsies at the New York Foundling Hospital. Last winter I saw a baby of 13 months in whom the symptoms were absolutely typical of adult typhoid. The spleen was very distinctly enlarged and the temperature ran a typical course. The Widal reaction was positive. The child even at that time was being breast-fed, and there was not a case of typhoid within a mile of the house, so we were entirely at a loss to discover the source of infection. I think we can safely claim that typhoid in infants varies very little from that seen in adults.

DR. H. M. MCCLANAHAN, Omaha—In reading the current literature of the past few months I was astonished to learn that there were only ten or eleven articles on typhoid fever in infants, a very important subject as compared with appendicitis in infants, with which we are all familiar, and about which a great many articles were written.

DR. E. F. BRUSH, Mt. Vernon, N. Y.—There was no doubt, in my mind, about this case being typhoid. What I can not understand, from the discussion, is, if typhoid is a water-borne disease, how the nursing babe can get it. I do not believe it can get it from its mother. My object in writing this paper was to call attention to the fact that the nursing infant did not contract the disease until it took the contaminated water, and that then it contracted the disease just as did the adults in the family.

DR. A. C. COTTON, Chicago—I do not think we should let this subject go out with the impression that children are exempt from typhoid, because they do not drink water. Children at the breast have typhoid fever; this has been demonstrated. A child may develop typhoid in utero, and nursing children have responded to the Widal test. That typhoid may be nursed from the mother's breast there seems to be little doubt; hence immunity for the breast-fed infant can not be claimed.

THE CLINICAL RESULTS OF SERUM THERAPY.*

EDWIN ROSENTHAL, M.D.
PHILADELPHIA.

A brief résumé of the various steps by which artificial immunization was finally brought about will prove one of the most interesting stories of medical history. To start with, the very first steps will bring us back to biblical lore, and in the Talmudical lore of the ancient Israelites we will find some striking rules that prove to the zealous investigators that the question of infection and contagion was equally as well known to them as it is to us. The rules of hygiene as set down by Moses have not been altered by time, and though the observations in that ancient period were not made with the exactness of the present time, the results were about the

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. Edwin Rosenthal, H. M. McClanahan and Samuel W. Kelley.

same, and if the rules were disregarded the same diseases were the results. The question of exactness is what is always necessary in any science, and though theory held sway for a considerable period, it was to the modern scientist that facts proved the truth of such theories.

THE GERM THEORY OF DISEASE.

The question of the germ origin of disease is not now a new one, and when Tyndall discovered in dust various microscopic objects it was not very long before the objects were isolated and their purposes investigated and proven. Probably immunity would remain at the present time the same theoretical subject had not Jenner made his "matchless operation" of vaccination and proven to the medical as well as to the intellectual world the wonderful efficacy of vaccination. From Jenner to Pasteur was but a step of time, and to Pasteur alone should credit be given for leading the way to practical serum therapy. We are all familiar with the various discoveries of this matchless investigator, and no greater honor can be given to such discoveries than having attached to them the name of their discoverer, and by that name to alone make known its object.

The Pasteur institute for the treatment of rabies demonstrates most practicably the clinical law of the application of serum therapy. For here to the most ignorant is demonstrated that rule: the early application of the remedy. Pasteur often applied his method of treatment to cases that he knew were hopeless, not so much for gain, nor for the failure that a failure should entail, but because he was such a whole-souled, noble-hearted man that he never could refuse. And hence, had Pasteur refused the use of his method to cases that have come to him too late the whole fallacious objection of those who do not understand the methods of his treatment would have fallen to the ground. As with Pasteur, so with Behring's, Roux's, Kitasato's, Marmorek's and the rest of these noble investigators' discoveries. History repeats itself.

THE AUTHOR'S FIRST EXPERIENCES WITH SERUM.

After Pasteur comes Koch, and when the discovery of this lymph was heralded to the world how entirely too much was expected of it! I remember when I had received a bottle of this priceless fluid, so rare and so difficult to obtain, I received offers of thousands of dollars for it. What I had received was enough for probably 300 injections. But, wishing that it should be placed to the best use, and not being so situated as to apply it as its value should direct, I gave half of my package to the University of Pennsylvania Hospital and the other half to the Home for Consumptives under the charge of Dr. William Muir Angney of Philadelphia. I can not tell with what anxiety I, with others, watched the results of these clinical experiments and what was our disappointment.

It was with the same feeling of disappointment that I welcomed the addition to our list of remedies: the antitetanus serum, then the diphtheria serum, the antistreptococcic serum, the antipneumonia serum and the like. I used the tetanus serum in a case of trismus neonatorum and the failure resulting dimmed my ardor for further clinical investigations on this line.

THE DIPHTHERIA SERUM.

But reading and studying never will cease, and when I read of the various investigations of Professor Behring I was as anxious to use this remedy as I had been with Koch's lymph. I wrote to my relative (one of the well-known alienists of Germany, Dr. A. Baer, physician to the Moabait) to get me some; it came; I was successful with my first case, and then even the cable was too slow. Now, was there an error in the method of my using the former remedies or was this one different? From Behring I obtained a personal monograph and this I followed, and the great truth came to me: that to use these remedies we must always use them in time. It is a mistake, or, I might say, the greatest mistake of all, to use any remedy of this class after a certain time. As an example, we should use the diphtheria serum in cases of diphtheria from its period of inception or incubation until that period where changes begin to take place, that is, in the first, second, third, fourth, or—even in a laryngeal case—the eighth day, or up till the time when the blood becomes changed and we no longer treat diphtheria, but its results. This is the greatest rule in the laws of immunity: we immunize against the disease, not its results. If we cure the disease we have no results. If we fail we have failed because the disease has changed, or, in other words, has become so far advanced that where we at first had a simple case of infection we now have an overwhelming result of blood change.

I have never failed with the use of the antitoxin if I have used it early enough and in sufficient quantities.

THE ANTISTREPTOCOCCUS SERUM.

Since the advent of the antitoxins other serums have come to our attention, notably Marmorek's serum. This serum is different from the antitoxin, for where in the former it was truly antitoxic, in the latter it is antimycotic. I have used this serum in many diseases the causative factor being the germ, that when properly prepared and injected into the horse or ass will give us a serum equally antagonistic.

I had greater opportunities to watch the results of the antistreptococcic serum than the diphtheria antitoxin. The simple reason is that in the case of diphtheria contagion the rules of the various boards of health interfere greatly, and in addition, there is the natural fear of the caretakers. No such conditions exist in sepsis, and again, the quality of the patients is different. In diphtheria we have children who have been suddenly infected. In septic cases we have the results of other conditions.

Now, while in diphtheria antitoxin we have had uniformity of results, it is not so with Marmorek's serum. Why is this? Take, as an example, erysipelas. This is the special disease that Marmorek originally reported as being treated and cured by his serum. It is true I have treated erysipelas—and I termed the cases "idiopathic erysipelas"—with this serum and have had very good results; but then again I have had a whole series of cases of erysipelas that I termed "surgical erysipelas," and have had such good opportunities of applying it, as, for instance, at the very beginning and at its height, but the results have been failures.

Now I have used this serum in puerperal fever and have had such good results that I reported the cases. I am persuaded that the serum was the factor of cure, as I permitted others, notably a well-known obstetrician (Dr. W. H. Wells) to make the diagnosis and prognosis. When again I used this serum in a case otherwise infected—probably of the same order as the surgical erysipelas, for the infection was made during an instrumental labor—and in a general hospital, my results have been failures. My attention being thus drawn to the peculiar method of this remedy acting, you can not charge me with being uncertain and again in doubt.

THE ANTITETANUS SERUM.

So with the antitetanus serum. I used it in an infant aged 6 days and in a quantity I thought sufficient, but

the results were always unfavorable. Dr. Biggs, to whom I always write regarding my serums and whom more than any one in America the profession should thank for his work in these lines, looks on these results as to be expected at this time. For example, the bacilli of tetanus multiply with such astounding rapidity that truly enormous amounts of the antitoxin should be used and in increasing ratio. As I used in proportion such small quantity the result otherwise could not be expected. Time will show us why this serum should give such good results in some conditions and failures in others; at present the theory of Biggs is the best propounded and should be accepted.

THE ANTIPNEUMONIC SERUM.

The last of the serums used by myself has been the antipneumonic serum. Now in my cases I chose the ones that I felt were somewhat hopeless—for instance, an infant who had suffered from measles and then from pneumonia. My second case was somewhat similar. Two instances were croupous pneumonia, simple—that is, with no complications—the others were pneumonia with pleurisy or bronchitis. In all there were nine cases. All good results. That is, all recovered; some may have taken longer than others, but such cases as pneumonia and measles I considered so very unfavorable that, since they had recovered, no matter how long the time, I was brought at once into the camp again of the serum-therapist. Then came a case of croupous pneumonia in an alcoholic. What now? My experience had been so uniformly unfavorable with this class of cases that I was glad indeed to have a remedy (?) on which I could place some little reliance. To this case I called Dr. J. C. Wilson, who has had a greater experience than mine with this serum. We used it according to the methods in vogue and used it fearlessly. After the ninth bottle (each one contains 20 c.c.) I desisted, and Dr. Wilson (we were making daily consultations) coincided. Now, in this case, the serum demonstrated its utter failure. We both knew all about the remedy and how to apply it. Why should it fail? This is one of the remarkable peculiarities of serum treatment. The remedy in many instances refuses to act. Wherein the trouble lies I have not been able to see or learn.

CONCLUSIONS.

This much I can say as a conclusion:

Diphtheria antitoxin is a specific and its standing is assured. It is only in exceptional and very, very rare instances that failures are to be seen, and this may be the result of the operator even as of the remedy.

Marmorek's serum is erratic and not to be depended on. It may be harmless as the originator asserts. Experience has also demonstrated this. If the method of its originator be followed in its application a favorable result or an unfavorable result may be equally expected. I think the failure of this remedy should be sought in the very original streptococcus used in the make of the serum. If this be found, and then the disease be isolated as well as the germ, we may have the same uniformity of results as in diphtheria. But so long as septic diseases depend on many germs, one germ in particular can not immunize.

I think the same failure results in pneumonia. Where the infection is mixed, failure results, not so much by reason of the remedy in the strepto-infection, but because the disease is complicated and the complication should require an especial addition to the serum, and this should be especially known. As long as this is uncertain so long should the rule be: Serum therapy should be applied under special conditions, and for special indications, and not empirically, as I fear the diphtheria antitoxin is being given.

517 Pine Street.

DISCUSSION.

DR. J. P. CROZER GRIFFITH, Philadelphia—At the time of the first interest in tuberculin a commission was appointed by the University of Pennsylvania to test its value. The investigation was carried on with the greatest precision and attention to systematic detail. It was my province to examine frequently the condition of the lungs in the patients under treatment. There was no case in which any decided alteration for the better was observed; and I am sure that in one case, which had for months been quiescent, the results were absolutely disastrous.

DR. A. C. COTTON, Chicago—I wish I could share the optimistic ideas of the essayist, but my experience with antitetanus serum has almost convinced me that its effect is practically *nil*. The fact that we treat a case of tetanus with serum and it recovers is little proof of the efficacy of such treatment. All of us who have seen many cases of tetanus, or who have watched the reports of such cases, know that many cases of tetanus recover. Most of us know, too, that there are cases of the so-called pseudotetanus of Escherich—a variety in which the symptoms are less marked and the case seems more amenable to treatment. Personally, I do not think that this good result indicates either the efficacy of the serum treatment or the necessity for this refinement of nosology. Tetanus may be intense and startling, or mild and subacute, and tetanus may recover under the ordinary sedative treatment. With an extended experience with tetanus I have come to the conclusion that my cases do just as well without the serum as with it, and this, too, although I tried diligently to convince myself of the value of this serum.

With regard to pneumonias in children, I must say that I do not consider croupous pneumonia the formidable disorder that many physicians believe it to be. If I can definitely locate a lobar pneumonia in a child I feel justified in making a favorable prognosis, and I am always glad to find that I am not dealing with a catarrhal pneumonia; hence it seems to me that serum treatment in croupous pneumonias yields clinical evidence of no great value. The large majority of these cases should recover with good hygiene and very little therapy. On the other hand, the uncertainties of catarrhal pneumonia are familiar to us all, and this disease, with its complications and sequelæ, renders serum treatment of questionable value.

DR. EDWIN ROSENTHAL, Philadelphia—I think the serums have proven themselves in the main misleading and disappointing.

THE USE OF GELATO-GLYCERIN BOUGIES IN THE TREATMENT OF ACUTE EARACHE IN YOUNG CHILDREN.*

GEO. L. RICHARDS, M.D.

OTOLOGIST AND LARYNGOLOGIST TO THE FALL RIVER UNION HOSPITAL.

FALL RIVER, MASS.

It is commonly stated that remedies applied to the external canal in the treatment of acute earache are of very little use, since, owing to the fact that the canal and tympanic membrane are lined with epithelium, which is an extension inward of the skin, the absorption is so slight that remedies of this class can do but very little good. While it is true that absorption is much less and slower than is the case when remedies can be applied to a mucous membrane, I am nevertheless fully persuaded that absorption of medicaments can take place through the external surface of the tympanic membrane, and that many remedies can be exhibited in this way to the comfort of the patient. In my early experience I

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. Edwin Rosenthal, H. M. McClanahan and Samuel W. Kelley.

often used morphin and atrophin solutions in the form of drops, and various oils and other external ear drops are in universal use.

Acute earache in young children is sudden and severe in its onset, and a remedy to be universally applicable should be one capable of quickly giving relief and easy of administration. When the inflammation has lasted for any length of time probably nothing short of a paracentesis will relieve; but there are many cases of sudden onset in which the timely exhibition of the remedy which I am about to describe will cut short the attack, relieve the child and effect a cure.

I refer to the use of gelato-glycerin bougies, in which the medicaments desired to be used have been dissolved. For their introduction I claim no originality whatever. They were first originated by the late Prof. Joseph Gruber of Vienna, and are familiar to those physicians who have been his students. He, however, does not tell how they can be made, either in his book on diseases of the ear or in his division of the Vienna formulary as given in Landesmann's *"Die Therapie an den Wiener Kliniken,"* and physicians who have obtained them of the Vienna apothecary recommended in Landesmann's book have not been able to get them made in a satisfactory manner in this country. In the *Journal of Laryngology,* January, 1898, R. H. Woods of Dublin gives a formula in which liquid extract of opium, cocain and atropin are combined with gelato-glycerin, and states that in his experience many cases of acute earache in children have been aborted by their use. He does not give in his article the proportions of gelatin and glycerin, but says they should be such that while remaining solid at the ordinary temperature of the air the bougie should melt at or a little below the body temperature, thus insuring their ready dissolution when placed in the ear.

I have taken the formula of Woods' as to the main ingredients, added thereto 3 per cent. of carbolic acid, for its anesthetic and antiseptic properties, and with the aid of my apothecary have overcome the pharmaceutic difficulties in their manufacture. I first described their use in the *Boston Medical and Surgical Journal* of July 28, 1898, and later wrote in regard to them in the *Laryngoscope,* August, 1899. My experience in their use now covers four years, besides which they are extensively used for the relief of earache by many physicians of my acquaintance, and in general with very gratifying results. Further experience has convinced me more than ever of their value, especially in the early stage of acute otitis media and in acute otitis externa.

It is on account of the extreme prevalence of earache in children that I have brought the subject before this Section, in the hope that you will try these bougies. They can be made by any druggist and have the advantage that they can be used without the slightest difficulty.

The bougie when prepared is either kept in a neutral powder like lycopodium or wrapped in tinfoil. To use, the lycopodium powder is washed off in warm water, or, if wrapped in tinfoil, they are dipped in warm water. The warm water aids in their solution. The bougie is then very slippery, and the affected ear being placed uppermost it can easily be slipped down into the external canal without the slightest discomfort to any child. Here the bougie soon dissolves, the anodyne is brought directly into contact with the inflamed surfaces and the pain is relieved. Beside being a medium for the exhibition of the opium, cocain and atropia, the glycerin is of itself distinctly curative, in that it tends to draw out serum from within and lessen the tension. A certain amount of osmosis takes place and there is, I think, absorption of the medicine contained in the glycerin. After insertion the ear should be stopped with absorbent cotton or gauze and a hot water bottle placed at the side of or over the ear. Even when paracentesis has been required and done I have found the insertion of a bougie immediately after the paracentesis to be of great relief to the patient in lessening pain and withdrawing serum and to have distinctly curative value.

Cases which have gone beyond an early stage are, of course, not relievable by this remedy, and demand treatment appropriate to the condition, whether paracentesis or otherwise; but many a case of acute earache will at once subside without going on to severe inflammation if promptly treated in this manner. Many mothers of my acquaintance keep these bougies in the house and use them at the slightest sign of earache.

The formula here given is a correct working formula and one that any pharmacist can use. My own druggist made them in a mold intended for urethral bougies and then divided each one into three. As this mold held just 14 urethral bougies the odd number of 42 is accounted for. After making they are covered with lycopodium powder or tinfoil and dispensed in a bottle, as, of course, they are somewhat hygroscopic.

℞. Acidi carbolici	minims	7
Fl. ext. opii	minims	6
Cocaini	grains	3
Atropini sulphatis	grains	3
Aquæ	minims	52
Gelatini	grains	18
Glycerini	grains	158

To make 42 bougies.

If desired the equivalent of morphin sulphate or acetate can be substituted for the fl. ext. opium.

In regard to their manufacture, dehydrated glycerin should be used. Several apothecaries have failed to make them, being unable to get the gelatin and glycerin to stiffen properly; but the problem is not a difficult one, as the bougies have been made with success in different cities by different apothecaries.

DISCUSSION.

DR. JOHN C. COOK, Chicago—I think the glycerin and carbolic acid combination has been used for a long time, and there is no question about its value, particularly when it can be so conveniently employed as in the form described.

DR. RICHARDS—When I showed these aural bougies at the Otology Section one gentleman said that there could be absolutely no absorption in the ear, while another gentleman said that these bougies were dangerous because there would be too much absorption. Another suggested that the gelatin and glycerin could be used separately, but it should be remembered that most of these cases are seen in the night, and these substances are not usually at hand, and the drug stores are closed, hence it is desirable to have something ready at hand.

Electrocution in a Public Bath.—The dangers of electric lighting were illustrated by a most deplorable accident in a London public bath. The attendants at the institution in question were attracted by the cries of one of the bathers, and on going to the spot found him in an agony of pain and suffering from shock, which shortly afterward proved fatal. Another man was found dead in an adjoining bath. The cause of death in both instances appears to have been electric shock. Pending an official inquiry into the occurrence, the probable explanation is that the baths became connected in some way with the wires conveying the current for lighting purposes. It is difficult to imagine any other way in which a powerful electric discharge could have reached the bath. The incident should attract the attention of all responsible for baths, both public and private, in every part of the United Kingdom. If the use of electrical lamps is to involve the risk of electrocution, then the public will undoubtedly prefer the substitution of less dangerous illuminants.—*Med. Press and Circular.*

A CONTRIBUTION TO THE SURGERY OF THE GALL BLADDER AND DUCTS.*

ALEXANDER HUGH FERGUSON, M.D., C.M.
CHICAGO.

ANATOMY.

The advancement of surgery to include the biliary passages has awakened a new interest in these structures and their relations. The surgeon found it necessary to go into the dissecting room and familiarize himself with the normal structures in this region. With this object in view, George Emerson Brewer,[1] M.D., New York, dissected and studied 160 subjects to which I wish to refer you. Mr. Morrison[2] has drawn attention to the lesser sac of the peritoneum in which the gall bladder exists, and many others have made valuable observations.

The ninth costal cartilage is the external landmark of the gall bladder; in making an incision to expose it, the lower intercostal nerves should be avoided if possible. By making the perpendicular incision below the costal arch, and through the outer border of the right rectus muscle, only the ninth intercostal nerve is severed. There is not much variation in the normal position of the gall bladder. In some instances (5 per cent.) it may have a double fold of peritoneum forming a distinct mesentery, affording considerable mobility. It is occasionally found almost buried in the liver, in the fissure between the right and quadrate lobes, so deeply as to be almost surrounded by liver tissue. Brewer observed it between two folds of the gastrohepatic omentum; I found it in this position in one case while operating.

Hochstetter[3] recorded a case in which the gall bladder was attached to the left of the median line and there was no transposition of the viscera. The position of the cystic, common and hepatic ducts, as well as that of the artery and vein, is fairly constant and so is the relationship to one another.

The greatest variation is in the arterial system; an arterial branch may be found crossing the ducts at any part of their course, or may run parallel with and to the outside of the common duct. The variation in length of the cystic (5 cm.), hepatic (4 cm.) and common (6.5 cm.) ducts, although considerable, is not important from a surgical standpoint. In diameter the ducts are as follows: Cystic, 2.3 mm.; hepatic, 4 mm.; common, 6.5 mm. This is important from a clinical standpoint. A stone that with difficulty passes the cystic duct, finds its way with ease through the common, till it reaches the duodenal orifice of the duct, which is smaller than any portion of it (3.8 mm.).

Owing to the spiral valve formation of the mucous membrane of the cystic duct, a probe can be passed only when it is pathologic, whereas a probe readily passes through the hepatic and common ducts.

On opening the duodenum, it is difficult to locate the ampulla by sight or touch on account of the valvulæ conniventes in this region. This may be faciliated by dilating the common duct with air or water.

It is well to remember that the gall bladder may be bifid, hour-glass shaped or absent; that the ducts may be represented by fibrous cords. A tongue-like process of the right lobe (Riedel) of the liver is a deformity to be considered as being occasionally present when making a diagnosis of tumors in this region.

DISPLACEMENTS.

In displacements of the liver the gall bladder is carried with it, and when it is tilted from above downward and backward, it presses on the gall bladder, also on the colon, giving rise to discomfort and pain, which vary with intestinal distention. One case of this nature was relieved by stitching the gall bladder to the upper angle of the wound opposite the ninth costal cartilage, which acted as a suspensory ligament to the liver. Although gallstones were suspected in this case before the operation, the gall bladder was not drained because it felt normal, and by pressing it on the under surface of the liver with my fingers its contents readily passed through the ducts, and by palpation no stones were felt in it, or in the ducts. In cases where the gall bladder is entirely surrounded by peritoneum there is great latitude of motion of this viscus. I have repeatedly demonstrated this by pushing it into the loin below the kidney, then bringing it just beneath the umbilicus, and finally to the left of the median line of the body. Such a gall bladder, owing to its dependent position and inability to completely empty itself, is prone to have stones form within it. For this reason it had better be anchored and drained. The most frequent displacements are due to some pathologic condition within the gall bladder itself, as in hydrops, or to outside adhesions to the stomach, duodenum, abdominal wall, omentum, appendix, or some portion of the intestines. The gall bladder that is held below its normal level by adhesions must necessarily contain more or less residual bile. The fixation and position prevent its regular evacuation. The result is that the bile becomes inspissated, cholesterin, bile pigments, germs and the other constituents of gallstones precipitate and become agglutinated together. This affords an explanation of cholangitis, there being incomplete emptying of the bile—residual bile—precipitation of stone-forming substances, trauma to the mucous membrane of the gall bladder, and finally infection, mild or severe, depending on the virulency and kind of germs present. Adhesions always begin at the area of inflammation. Should the gall bladder be inflamed, adhesions formed with contiguous structures tend to drag these to it. The contrary is the rule when an inflamed appendix, bowel, etc., come in contact with the surface of the gall bladder. There are many other factors that displace the gall bladder, such as occupation, tight lacing, etc.

GALLSTONES.

The life history of a gallstone from its formation to the time of its impaction has not yet been fully written. Cholelithiasis is materially within the scope of laboratory workers and clinicians, and we look to both to unravel the etiologic mysteries of its prodromal stages. This much may be said regarding their formation: Catarrhal conditions of the mucous membrane of the gall bladder and ducts, excited, of course, by the presence of microbes, produce both cholesterin and calcium salts (Naunyn). Germs and gallstones are very frequently associated together (Welch)—the germs occupying the center of the stones. It has been shown that *B. coli, B. typhosus,* the staphylococcus and streptococcus occur and live in the gall bladder for a long time (seven years for typhoid according to Blachstein). Gallstones can be produced experimentally by injecting germs into the gall bladders of dogs (Gilbert). There are other causes accessory to the above.

3. Arch. f. Anat., Leipsic, 1886.

Age.—While they have been found in persons of all ages, they are rarely met under 25 years. Fully 50 per cent. of all the cases occur about 40 years of age.

Sex.—Gallstones are over three times more common in females than in males, and more common in women who have borne children.

Occupation and Habits.—Certain kinds of work which require the forward bending of the body, thereby causing enteroptosis, displace the gall bladder and predispose to the formation of gallstones. Gastrointestinal disturbances, indigestion and constipation play a passive part in their formation. Tight lacing comes in for a good share of the blame. The lithic diathesis is prominent in those who overindulge in food, or are mentally depressed or insane.

CLASSIFICATION AND COMPOSITION OF STONES.

They may be classified: 1, cholesterin stones; 2, cholesterin-pigment stones; 3, biliary-pigment stones; 4, carbonate of calcium stones. This is according to their composition. The cholesterin-pigment stones are the most frequent, as might be expected from the larger amount of cholesterin (75 per cent.) and pigment present in bile. A pure cholesterin stone is rare, and so is the calcium carbonate one. Although gallstones may form in any part of the biliary passages, even within the liver itself, in the shape of small ovoid greenish-black grains, still the vast majority form within the gall bladder and there remain or find their way into the larger ducts.

Special Properties.—Gallstones vary in color, size, shape, consistency, number and weight. When composed of pure cholesterin they are almost colorless, and the color darkens according to the amount of pigment entering into their composition. One calculus or several thousand stones may be packed into the gall bladder and ducts, varying in size from that of a grain of sand (gall sand) to several inches long. They may be round, ovoid, barrel-shaped, bullet-shaped, triangular, nonfaceted or faceted in one or many places. I have seen them take the shape of the gall bladder or portion of the duct where they were impacted. If composed principally of amorphous cholesterin the stone is soft, and can be broken between finger and thumb, but when the cholesterin is in a crystalline state, and especially if earthy salts enter into its composition, it is quite hard and can not be broken as above mentioned. A mixed gallstone is not much heavier than the bile itself, hence feeble contractions of gall bladder and ducts and a slow flowing stream of bile are sufficient to carry it to and fro in the passages.

A gallstone increases in size by additional layers forming on its external surface. It is not uncommon to find a stone in a duct a dozen or more times larger than the normal size of the duct in which it is contained. The last stone I removed from a common duct was ¾ inch in diameter and 1¼ inches long.

Intestinal obstruction is sometimes caused by a large gallstone. The manner of growth is best manifested by making a section of a gallstone. The center shows a nucleus consisting usually of bile-pigment and cellular debris. Around the nucleus are concentric laminæ with radiating lines from center to periphery. These layers are principally composed of the envelope-shaped crystals of cholesterin held together by mucus.

SYMPTOMS AND SIGNS OF CHOLELITHIASIS.

The routine recitation of the symptoms and signs of cholelithiasis, as found in the medical and surgical textbooks, is of very little value to the practitioner, student or clinician. The most characteristic evidences of the disease are manifested by suffering and jaundice, with their associated symptoms and signs. The sudden onset of regional pain and tenderness, with or without apparent provocation, lasting from a few minutes to several hours, with little or no pyrexia and normal or slow pulse; the pain and tenderness stubborn in yielding to applications of moist heat or internal medication and subsiding as suddenly as they began, *is a clinical picture of a stone or stones becoming impacted in the cystic duct and again receding into the gall bladder.* The posture sense of the pain is undoubted by the patient, and the higher sensibility in the gall bladder guarded by a tense right rectus muscle is easily demonstrated by the surgeon. The pain usually is sudden in its onset; its seat is sometimes far distant from the gall bladder; it often follows some exertion which increases the intra-abdominal pressure; may last for ten or more days; fever may be high from the start; and the subsidence of the pain quite gradual. In my experience the following order of frequency of pain may be referred to: (*a*) pit of the stomach; (*b*) the back near the angle of the scapula; (*c*) umbilicus, and (*d*) to different parts of the abdomen and body. But when the surgeon makes pressure over these places, very little or no tenderness is complained of, at which the patient expresses surprise. *Pressure over the gall bladder during an attack of colic always elicits local tenderness and increases the intensity of the local and referred pain.* The pain is intense while the stone is traversing the cystic duct, and suddenly becomes less severe in character when the concretion has either dropped back into the gall bladder or entered the common duct. Should the pain continue and jaundice ensue, the stone is evidently obstructing the main duct, but if sudden relief is experienced no doubt the stone has found its way into the duodenum. The pain usually becomes excruciating when a calculus is passing through the ostium duodenalis, the narrowest part of the ductus communis choledochus. The attack is now over and the jaundice clears away in a few days. There is a wonderful variation in the character and severity of the pain, and the constitutional effects differ very materially in individuals. It saps the courage of the bravest patients and "doubles up" the most robust and strong-minded individuals. Like many other acute suffering affections, where pain is the prominent subjective symptom, it disturbs all the great systems of the body, some to activity and others to retardation of function, and even death ensues at times.

In cases demanding operation, biliary colic may be present without gallstones, and gallstones may be present without biliary colic. I have opened the abdomen several times in search of gallstones and found none. In some of these the gall bladder was distended with bile and displaced medianward. The colic was well marked, severe in the one case, while in another, an aged lady of 70 years, it was so marked as to cause collapse and grave symptoms of sudden dissolution. A cholecystotomy cured them. I have termed this condition[4] in these cases "flexion of the gall bladder."

In several cases, inspissated bile, dark in color, and of a tarry consistency, filled the gall bladder and occluded the cystic duct. It was thick and tenacious and had to be scooped and mopped out. No gallstones were present. These had suffered repeated attacks of colic, some of them for years.

In other instances the gall bladder was converted into a retention cyst and it contains principally clear mucus.

4. British Medical Journal, Nov. 6, 1897.

The gall bladder is very tense and hard, there being a fibrous occlusion of the cystic duct.

In sixteen of my cases there was no clinical history of gallstones except gastrointestinal disturbances; twelve of these had dropsy of the gall bladder and the stone or stones in each were very large and latent, producing no pain. The gall bladder was greatly enlarged in each. An interesting case of gallstones without biliary colic was one of partial empyema of the gall bladder, with an extramural chronic abscess situated in the lumbar region, very much resembling a sarcoma. A large stone was impacted near the fundus of the gall bladder, dividing it into two cavities, a proximal space containing normal bile with large and small latent calculi, and a distal cavity at the fundus containing pus and communicating with the abscess cavity in the lumbar region. In 6 per cent. of my cases of chronic obstruction of the biliary passages, pronounced colic was absent, but in all of these there was a history of indigestion, constipation and colicky pains years ago, of short duration and judged to have been caused by food or exposure to cold.

It may be said that one attack predisposes to subsequent attacks. A variable time may elapse between them, even years. It appears to me that the more chronic a case is the more frequent and less severe is the colic. In several cases of chronic impaction the pain became almost constant, but not severe. From two to eight or ten attacks per day were not uncommon, the patient becoming completely incapacitated.

The causes of advanced biliary colic are: (1) spasm of the muscular fibers of the gall bladder and ducts; (2) forcible stretching of the duct wall; (3) spasms of the rectus abdominis muscle; (4) emotional disturbances; (5) inflammatory swelling of the mucous membrane of the ducts (Riedel), and (6) one authority goes so far as to say that "The so-called gallstone colic is suppuration of the gall bladder." This is a mistake. If it were so we should meet more frequently with cases of inflammation, ulceration, empyema and gangrene of the gall bladder. The fact is that in over 50 per cent. of my cases of gallstone colic no germs were found in the bile taken from the gall bladder and ducts. In my opinion, the local pain of cholelithiasis is mainly caused by two factors: first, by spasm of the muscular fibers of the ducts and gall bladder; and, second, by the stretching of the ducts and gall bladder. When the gall bladder and ducts become fibrous and so pathologic as to lose the power of contraction, then the stretching is the sole cause of the pain. There is no hollow viscus or tube in the whole body that can be forcibly over-distended or over-stretched without causing pain, whether that organ or passage be normal or diseased.

DEMONSTRATIONS.

I have repeatedly tested the sensibility, distension and contractibility of the gall bladder and ducts.

The first case on whom I demonstrated the cause of the colic to be over-stretching of the gall bladder and cystic duct was a Mrs. C., on whom I performed a cholecystotomy April 20, 1895. The operation was performed in the then recognized way, and an external biliary fistula followed, which I cured by a plastic operation August 10 of the same year. Between April and August I repeatedly sounded the cystic duct, mechanically irritated the inside of the gall bladder and over-distended it with water. Any quantity of warm water would pass through the ducts under low pressure, but whenever the douche bag was elevated, rapidly increasing the pressure and quantity of water entering the fistula, the gall bladder became filled to over-distension, because the inflow was greater than the outflow through the cystic duct, producing there and then her old-time typical gallstone colic. The pain was local, over gall bladder, and referred to the umbilicus and between the shoulders, just the same as before the operation. The passage of a small flexible bougie into the cystic duct gave rise to no pain until stretching occurred. The rubbing of the inside of the bladder with probes and bougies gave no inconvenience, but just as soon as an olive-pointed bougie or sound a little larger than the caliber of the cystic duct entered its orifice the typical colic of gallstones suddenly came on. These experiments I have repeated many times. From this I conclude that the spasm is an etiologic factor in gallstone colic when the power of contractibility is still present. When the bladder and ducts are fibrous, hard and firm, no pain is produced in them except by stretching. The etiology of the biliary colic may be schematically presented as follows:

CAUSES OF BILIARY COLIC.

The primary causes are: 1. Over-distension and stretching of the gall bladder and ducts. 2. Spasm of muscular fibers of the biliary passages. The secondary causes are: 1. Tonic contraction of the right rectus abdominal muscle, pressing an over-distended gall bladder. 2. Infection, causing inflammatory swelling. 3. Cancer of the gall bladder and ducts intensifying and continuing pain.

Vomiting is a common sign of biliary colic and is often very troublesome. It usually follows the pain, and is acute, the stomach contents, mucus and often bile coming up. When bile is vomited in jaundiced cases it shows that the obstruction of the common duct is not complete, and then biliary pigment can be found in the stools. When blood is vomited some gastric disease may be looked for. The vomiting in twelve of my chronic cases of gallstone impaction with jaundice became a daily occurrence and so easily provoked that no solid food could be taken. When the kidneys are diseased the vomiting is more persistent and frequent. If large gallstones are found in the vomited matter it is evidence of a fistula having formed between the gall bladder or biliary ducts and the stomach.

Nausea accompanies some chronic cases of vomiting and is provoked by the slightest pressure over the impacted stones. Clay-colored stools have long been recognized as caused by complete obstruction to the flow of bile. If small gallstones are found in the stools during or following the attack of suffering, they have escaped from the gall bladder and ducts per via naturales. If they are larger than what possibly can pass the ducts, then most likely they have come into the bowels through a fistula formed by means of pressure atrophy or ulceration. Enteroliths composed principally of gallstone material (cholesterin, etc.) sometimes obstruct the bowels. Indigestion, constipation, irregular tympany, cough, nervousness, emaciation, etc., are other signs of cholelithiasis.

In cholelithiasis jaundice is either acute or chronic, caused by absorption of the bile by the lymphatics. It is the most certain and frequent sign of an obstructed common or hepatic duct. It occurs in rare instances when no stones are in these ducts. I have seen the hepatic duct blocked with echinococcus cysts causing jaundice. Cases are reported where a large stone or stones in the gall bladder or cystic duct pressed on the common duct so as to obstruct the flow of bile. It is frequently caused by inflammatory swelling of the mucous membrane. It is not my experience that two-fifths of the

cases occur in this way, as stated by Riedel. On removal of the obstruction by operation, air or water may be forced into the duodenum. Immediately after relieving impaction of the ducts the quantity of the bile pigment in the urine decreases in some cases before inflammatory swelling could subside. I must say I have seen the jaundice deepen for two or three days after an operation. I have also noticed "suppression of bile" for several days after cholecystotomy. This may have been congestive swelling obstructing the ducts or caused by shock.

Beautiful theories as to the cause of jaundice have been advanced, based on the disturbance of liver cells (Liebermeister) and reflex nervous influences (Pick). When jaundice is not present in gallstone colic, we should not wait for its appearance before recommending an operation. It may never appear. The patient may suffer attacks for years with no jaundice, and it is often found that the stones in the gall bladder were too large to ever pass through the ducts. An interesting case was met by myself and others in which the common hepatic and large branches of the intrahepatic bile ducts were filled with calculi and still distinct jaundice never appeared. The bile must have trickled through between the stones. It is not an infrequent occurrence for bile to escape for a time around a large stone in a duct. The disappearance of jaundice in an acute case of colic does not, in the vast majority of cases, mean that the stone or stones have passed into the intestines and that spontaneous cure has resulted. Repeated attacks of jaundice with absolute freedom from it between the attacks is rather indicative of a supply of calculi within the gall bladder. Chronic obstructive jaundice, with attacks of colic, is necessarily incomplete; hence it may last for months or even years without causing death. Repeated acute exacerbations of jaundice engrafted on a chronic jaundice are indicative of a stone shuttling to and fro in the common or the hepatic duct. It is known as ball-valve action (Fenger). In one of my recent cases a stone was plying in the cystic and common ducts, causing colic and jaundice, the latter entirely disappearing between the attacks. The chronic jaundice of gallstone obstruction is characterized by improvements and relapses lasting indefinitely without producing profound cholemia, which is of clinical value in contradistinction to the chronic jaundice due to malignant obstruction of the common duct. The presence of bile in the urine is often the first sign of approaching jaundice.

Itching is a symptom of jaundice and universally affects the skin, frequently disturbing the patient at night. It is not always present and is obstinate to local applications.

In acute biliary colic, arising from a stone in the cystic or common duct, the liver dulness is increased. I have seen it extend to the level of the umbilicus. A local perihepatitis manifested by local pain and friction is sometimes present in cholecystitis and cholangitis. When the liver is enlarged, but not tender, the increased size is evidently due to the engorgement of the intrahepatic bile ducts.

Enlargement and distension of a normal gall bladder are always present in acute impaction of a stone in the cystic duct. In dropsy of the gall bladder, in retention cyst, in acute and chronic empyema of the gall bladder, in acute phlegmonous inflammation of it, and in impaction of many stones in the gall bladder it is enlarged. I have seen the gall bladder enlarged by great fibrous thickening resulting from colon bacillus, making it difficult to differentiate it from carcinoma macroscopically. In chronic impaction of the ducts the gall bladder becomes contracted and tender. It is well to recollect that in cases of chronic jaundice with or without a history of cholelithiasis and the gall bladder enlarged, the obstruction of the common duct is usually malignant.

The rise of temperature during biliary colic took place in about 52 per cent. of my cases. The fever begins after the pain and a chill may accompany it. It usually ranges from 99 to 101 F., but may reach 103. The pulse rate is not accelerated in proportion to the rise of temperature, but is often lowered. This biliary fever is still an enigma. It sometimes exists when no germs are present in the bile, but this does not exclude infection. The absorption of biliary constituents may account for it. In partial support of this view I wish to refer to a case[5] operated on on the 6th of July, 1896. In this case the gall bladder was perforated by a stone and the peritoneal cavity filled with bile. The temperature ranged from 99 to 100 F. for six days before the operation, and it subsided on washing out the peritoneal cavity and emptying the gall bladder of stones and bile. No germs were found in the bile. The "intermittent hepatic fever" of Charcot is found in certain chronic cases. In the presence of jaundice it is to be distinguished from malaria. The "chills and fever" occur sometimes with ague-like regularity (Osler). The fever is not changed by quinin, the spleen is not enlarged and no parasites are in the blood.

MEANS OF DIAGNOSIS.

1. *Evidence, Direct and Indirect.*
2. *Inspection, Palpitation and Percussion.*
3. *Deep Prod.*—Mr. Jordan Lloyd tersely described the value of giving a prod over the gall bladder with the closed fist, and if gallstones are present, considerable pain may be caused. It is a procedure of considerable value.
4. *Auscultation.*—By listening over the gall bladder the friction sound of local peritonitis and perihepatitis is detected, and thus the extent of recent inflammation may be defined. During the acme of colic the gallstones can occasionally be heard striking against each other. I did not believe this until 1889. I had a patient who passed through the hands of "Christian science healers" who did not consent to surgical interference. For twelve years she had suffered from gallstone colic in an intermittent manner and the last fourteen months of her life with persistent jaundice. The gall bladder was enormously enlarged, and the "rattling of the stones" could be heard while standing by the bedside. This peculiar sound was to her mind an omen of Nature's effort to break up and melt the stones.
5. *Examination of Blood and Urine.*—An examination of the blood for leucocytosis is of value in differentiating cholelithiasis, or in recognizing infection of the gall bladder and ducts as a complication. Examination of the urine very frequently reveals a trace of bile in obstruction of the cystic duct, even when there is no jaundice present, which is of value in making an early diagnosis of gallstones.
6. *The X-Ray.*—The Roentgen ray has not been of very much aid in my cases, but it appears to have been of value in the hands of others. It is to be hoped that this means may become of more value.

GANGRENE OF THE GALL BLADDER.

Gangrene of the gall bladder is sufficiently uncommon to justify me in reporting two cases, one due to infec-

5. Medicine, August, 1897.

tion and the other caused by over-distension of the gall bladder.

CASE 1.—Mr. J. W. S., age 59, merchant of Syracuse, Ind., April 3, 1898, was seized with biliary colic and called Dr. B. F. Hay of that town to relieve him. His pulse and temperature were normal, the pain was intense, only relieved by frequent hypodermic doses of morphin and local applications of hot moisture. A tender swelling, dull on percussion, was felt under the right costal arch. The liver dulness was enlarged and the area tender. On the evening of the third day the smouldering pain became infuriated to intense seizures of suffering, causing him to complain even when profoundly narcotized with morphin and abdomen covered with hot stupes. Slight tympany, a rise of temperature to 102, an increased pulse rate of 110 to 120 per minute and slight jaundice ensued. On the sixth and seventh days the tympanitis increased and extended over the tumor and lower border of the liver, the pulse and temperature remained about the same. I was summoned on the seventh day, and on arriving found that he had died about half an hour previously.

The temperature was at its lowest degree (100 F.) an hour before death, and the highest (105.2) ten hours previously, at which latter time the pulse was 120 and the respiration 32. His urine passed involuntarily, and he was unconscious nearly all the time, speaking distinctly once, eighteen hours before death.

Previous History.—With the exception of occasional slight and insignificant colicky pains in his stomach during the last two years, lasting but a few minutes, he has enjoyed the best of health.

Postmortem.—The findings in the abdominal cavity were as follows: A full length median incision allowed coils of distended bowel, normal in color, to protrude. On passing the hand adhesions were felt in the right lumbohypochondriac region, and nowhere else. A transverse cut through the right abdominal wall to the lumbar region fully exposed the pathologic condition. The right and upper border of the omentum was red, swollen, covered with thick lymph, overlapping the colon and gall bladder and adherent by delicate adhesions to these structures and to the parietal peritoneum and liver. An abscess was situated in the right lumbar region a little below the end of the twelfth rib, and contained about an ounce of pus. A suppurating track led from it to a perforation in the gall bladder on its anterior surface near the end. The edges of the perforation in the gall bladder were black and gangrenous looking. The gall bladder was about twice the normal size, tense and edematous to the touch, livid in appearance, with black spots showing through in many places. It had the manifestations of an advanced stage of acute phlegmonous inflammation. It was sausage-shaped and extended along the under surface of the liver beneath the costal arch. The adhesions surrounding it were very friable, and these being broken down, dark-colored fluid oozed from the surrounding tissues. The gall bladder was now opened. It was filled with dark-colored bile and 776 stones, varying from the size of half a grain of wheat to a large bean. The mucous wall of the gall bladder was gangrenous in many places, which here and there showed through all the coats of the viscus.

The ducts were laid open and found normal. All the other organs in the abdominal cavity appeared normal, even the vermiform appendix.

Bacteriologic Examination.—In Professor Kleb's laboratory at the Postgraduate the contents of the abscess and the fluid contents of the gall bladder were subjected to a bacteriologic examination. The former contained many slender bacilli of different lengths, mostly in chains, streptobacillus of pus and a few cocci, and the latter was found to have in it the *Bacillus coli communis.*[6]

CASE 2.—Mr. A. M. P., age 43, referred by Dr. Gentles; entered the hospital March 22, 1902, complaining of:

1. Slight pain in the right hypogastric region.
2. Tumor in region of gall bladder increasing in size.
3. Temperature 102 F. (rose from 99 in 3 hours).
4. Loss of appetite.

6. This case was published in Chicago Medical Recorder, May, 1898.

History of Illness.—March 12 patient came to Dr. Gentles complaining of uneasiness in the stomach. Tongue slightly coated. The uneasiness bore no relation to the digestion of food. On palpation a small tumor was discovered at the site of the gall bladder, the size of a walnut. This was almost painless on deep pressure.

March 16 patient returned unchanged. March 20 the gall bladder was somewhat increased in size. March 21 patient had an attack of acute pain which was relieved by morphin sulph. gr. ⅛. On the morning of March 22 the bladder was distinctly enlarged. Operation was advised and patient removed to the hospital.

Physical examination revealed a tumor in the region of the gall bladder, hard on palpation, movable and directly traceable from an inch above the level of the umbilicus to the lower border of the liver. The patient is a large corpulent man who has always been healthy.

Operation.—An incision was made over the tumor. The gall bladder easily found, very much enlarged and the upper third gangrenous. In color it was black, the luster of its peritoneal coat lost and in two places its coats were thin and would certainly rupture before long. The gangrene was evidently caused by over-distension of the gall bladder. On aspiration about 15 ounces of a black thick fluid were removed. Then several scoops of small gravel were removed. The gangrenous portion was cut away and the healthy part sutured to flaps of peritoneum and transversalis fascia.

Drainage tube inserted into the gall bladder surrounded by plain gauze. Gauze strips were placed from the anterior wound to the foramen of Winslow. Another drainage tube was inserted through the lumbar region to the foramen of Winslow. The incision was closed with silkworm gut.

After-treatment.—On the first day the temperature was 102.2 and pulse 112. On the third day the temperature was 99, and remained normal throughout. The wound was dressed first on the sixth day, and after that daily. During the last week in the hospital a slight quantity of pus was discharged from the superficial tissues.

Four weeks after the operation the patient left the hospital with a small fistula. Ten days later a slough of a major portion of the gall bladder came away through the fistula, and six days later it was completely closed. The contents of the gall bladder were sterile. His recovery is complete.

OPERATIONS DURING THE ATTACK IN BILIARY COLIC.

Waiting for the attack to pass off proved fatal in two cases that came under my observation, one of acute phlegmonous cholecystitis and gangrene of the gall bladder.[7] The man was ill for seven days with exaggerated symptoms and signs of obstruction to the cystic and common ducts, and also with undoubted evidence of infection, although he had for a couple of years colicky pains in his stomach, off and on, not deeming them of sufficient importance to consult a physician. This attack was his only severe one, and it killed him because he would not consent to an operation.

In another case death was caused by the severity of the colic. I had removed several small myomata from her uterus three days previous to the attack of colic which ended her life in six hours. This woman had a history of cholelithiasis, but refused operation. While waiting for the attack of the colic to pass off she sank and died from shock. The only pathology revealed by a postmortem examination was an over-distended gall bladder which contained bile, mucus and three enormous gallstones.

If infection is present, the sooner the gall bladder is uncompromisingly attacked and drained the better. In a well-marked case of biliary colic let it be even the first attack, the gall bladder enlarged, tender, etc., I can see no scientific or reasonable objection to the removal of the gallstones there and then during the attack.

7. Chicago Med. Recorder, May, 1898.

Early operation shortens suffering, prevents complications and obstruction of the ducts. No case should, in my opinion, be allowed to become chronic. Early gall-bladder surgery is safe and easy, while late operations are dangerous and difficult. The physician has no assurance from clinical experiences or pathologic findings that in a given case the attack will subside without causing (*a*) jaundice by obstruction of the common duct, which may remain until relieved by a serious operation; (*b*) rupture of the gall bladder; (*c*) ulceration and perforation by pressure of the stones; (*d*) death by the severity of the colic; (*e*) empyema, and (*f*) acute phlegmonous inflammation and (*g*) gangrene.

Treatment.—I shall not discuss the treatment at length, because it is fairly well established from a surgical point of view.

Incision.—The straight incision through the abdominal wall entering opposite the ninth costal cartilage and extending perpendicularly downward through the external border of the right rectus muscle is the one I make in preference to all others. It gives sufficient room in dealing with all conditions of the gall bladder. In removing stones from the cystic and especially from the common duct more room is often required; then from the upper angle of the straight incision cut upward and inward to the ensiform cartilage, severing skin, anterior and posterior sheaths of the rectus muscle, but not the muscular fibers or peritoneum, for they will stretch. This extension from the upper end of the straight incision affords ample room for all surgical procedures on the cystic and common ducts except the duodenal orifice.

PALPATION OF THE GALL BLADDER AND DUCTS.

The abdomen being opened the gall bladder is best palpated by two forefingers of the right hand. It feels soft and resilient when it is normal, and then by gentle but firm pressure on it against the liver it is readily emptied of its contents. Abnormal positions of the gall bladder are then looked for, and should flexion at its neck be detected it must be corrected by fastening it to the upper angle of the wound and thereby prevent it from again doubling on itself. It is astonishing the grave attacks of colic that may be caused by simple flexion of the gall bladder. Should the case be chronic, even though no stones are felt in the gall bladder and its contents readily pass through the ducts into the duodenum, biliary sand, catarrhal cholecystitis or atony of the muscular coats of the gall bladder is likely present and then the gall bladder should be drained externally. When gallstones are present in the gall bladder they can usually be palpated; should the gall bladder be very tense, aspiration of its liquid contents may be necessary before the stones can be felt. The gall bladder is in certain chronic cases so thick from inflammatory attacks that nothing can be felt but a cicatricial mass in the region of the gall bladder with old adhesions surrounding it, through which no stones are detectable. The mass must be split open to find them.

PALPATION OF THE CYSTIC, HEPATIC AND COMMON DUCTS.

This is best performed by the left hand, the surgeon stationing himself on the left side of the patient. The two forefingers of the left hand are passed into the foramen of Winslow behind the ducts with the thumb coming immediately in front of them when a stone in the cystic, lower portion of the hepatic, or in the common duct, except at the ampulla of Vater, is palpable between the thumb and fingers.

HOW TO ASCERTAIN THE PATENCY OF THE DUCTS WHILE OPERATING.

Probe.—A probe will not pass through a normal cystic duct on account of the spiral valve-like formation of its mucous membrane, but it can be easily passed through the common. On opening the gall bladder and emptying it of stones, bile, etc., it is often necessary, before complete work can be carried out, to ascertain whether the ducts are obstructed or not. A probe may detect a stone in them, but should you be unable to pass it through the cystic it may be open for all that, i. e., it may be normal or strictured, and for this reason the probe is unreliable.

Water.—I have frequently proved the patency of the ducts by forcing water through them. It will pass through ducts that allow the conduct of bile. An ordinary rubber bulb syringe is all that is required for this purpose. It is easy to use water by inserting the nozzle of the syringe into the incision in the gall bladder and tightening the viscus around it so as to prevent the water from returning and thus test the patulency of the cystic and common ducts. The quantity of water that passes into the bowel can be reckoned. For this purpose I have devised a special instrument which I here exhibit. On completing the test some care is required to prevent wetting the surrounding parts.

Air.—Dr. Van Hook was the first to employ air for testing the patency of the bile ducts, and he devised an instrument for this purpose. Air has the advantages of being always available, practically pure and it quickly balloons the duodenum. One squeeze of the same rubber bulb that I used for water will at once bulge up the bowel with air when the ducts are open. No special apparatus is necessary. The air test is the quickest, most satisfactory, and any rubber bulb that holds four or six ounces may be employed. It also requires less force to pass it.

CHOLECYSTOTOMY.

Incising, emptying, draining and suturing the gall bladder in place is usually not difficult. Of all the operations at our command for the treatment of gallstones, cholecystotomy has the widest range of usefulness. When properly performed with an understanding of its indications and limitations the results are excellent. In emptying the gall bladder of mucus, bile and pus a suitable trocar and cannula is the most efficient. I then wash out the gall bladder with an instrument so constructed as to allow a return flow, with water at the temperature of 115 to 118 F., and finally force the water out with air and thus prevent the water from wetting the wound or surrounding packing. No soiling of the peritoneum or wound should be allowed no matter what may be the contents of the gall bladder. Let the operator take it for granted that everything within it is capable of infecting the patient.

For the removal of stones I find that scoops of different sizes do the work most quickly and safely. The gall bladder should, in order to prevent a biliary fistula, be sutured to the inner aspect of the abdominal wall and at the upper angle of the wound. It should not, as we used to do, be sutured to the skin, nor to the lower angle of the wound. It is my practice to drain most every gall bladder that I open. There are several reasons for doing this. The first is that virulent germs may be present, and this can not be ascertained while operating. Second, catarrhal, ulcerative and inflamed conditions are also often present, which are best treated by drainage. The traumatism caused by the operator to the gall bladder itself, while removing gallstones from it, produces a

certain amount of hemorrhage and oozing of blood serum which had better be allowed to escape externally.

The drainage rubber tube is protected with gauze, and care is taken that it does not engage the cystic duct. If the end of the tube is grasped by the duct, the patient suffers from colic immediately after the operation. The operation of cholecystotomy by two stages seems to me quite uncalled for. It is not suitable for the most difficult cases of impacted gallstones, where deep jaundice or infection is present, and for the easy cases I can see no object for delaying the opening of the gall bladder at once. The drainage tube may be removed in four or five days should the bile be sterile. The indication for the permanent removal of the drain is the sterility of the fluid material coming away. The gall bladder should not be packed with gauze.

Cholecystopexy and cholecystendysis are fast becoming obsolete, and are procedures hardly worthy our deliberation.

CHOLECYSTENTEROSTOMY.

This procedure has a limited field of application. The chief indication for which this operation was devised—the cure of biliary fistula—no longer pertains because it is prevented by the proper performance of cholecystotomy. Should, however, the common duct be completely obstructed by cicatrization or malignant growth and a permanent biliary fistula thereby inevitable, then cholecystocolostomy should be performed.

CHOLECYSTECTOMY.

The removal of the gall bladder is indicated in primary carcinoma of that viscus, and when it is perforated in many places by a phlegmonous (gangrenous) inflammation. It is not even necessary to remove the gall bladder for retention cysts, because Drs. Mayo of Rochester, Minn., first published and demonstrated that the removal of the mucous membrane is all that is required. It is a simple and safe procedure. In cases of large retention cysts, and especially in hydrops of the gall bladder, its removal with its contents is surgical and comparatively easy to perform. When it is deemed best to give rapid escape to the bile, as in cholemia, the gall bladder had better be used for drainage purposes if for nothing else.

CHOLEDOCHOLITHOTOMY.

This is the removal of a stone or stones from the common duct. It has been performed in three different ways: First, by attacking the duct from the right of the duodenum, known as the external route. The second is exposing the duct from the left of the duodenum, and the third method is the transduodenal. The second of these has been properly discarded. So much has been written and said about choledocholithotomy that it is unnecessary to repeat it here, and the transduodenal route is only suitable when the stone is impacted in the ampulla of Vater. Stones in any other part of the common duct can be removed by exposing it to the right of the duodenum. Suturing of the common duct, after the removal of a stone or stones from it, is not at all necessary. I have demonstrated to my own satisfaction that the duct will close within three or four weeks, and all that is required is to have Morrison's pouch and the opening in the duct completely drained.

In removing stones from the cystic duct an effort is first made to force them back into the gall bladder; failing in this even after dilatation of the neck of the gall bladder, the stone or stones must be cut out. It is best to cut the peritoneum parallel to and above the duct and then open the duct on its upper surface. The peritoneal flap is then returned and sutured in place.

HEPATOTOMY.

Incising and draining the liver in certain cases of gallstone impaction with jaundice and cholemia is a procedure advised and practiced by Dr. W. E. B. Davis[8] of Birmingham, Ala. Dr. Davis said: "The point I want to make particularly is this, that in those cases where we can not reach the gall bladder or the main ducts, we should open the liver and drain it for biliary obstruction. After the patient has recovered from the cholemia and exhaustion, if the duct has not been cleared, a radical operation should be undertaken for the removal of the obstruction." It is a procedure worthy of further trial. It served me well in one case of cholemia.

DISCUSSION.

DR. W. J. MAYO, Rochester, Minn.—As to the question of exposure: Robson is in favor of making a space large enough to draw the liver well up and out with the hand, exposing the ducts; Lange severs the costal cartilages to increase the room; in our experience, by cutting the gall bladder loose from the liver it can usually be drawn out of the wound, exposing the ducts. This allows the liver to recede and gives more room. As to adhesions: I would warn against their extensive division in acute infections, if they are not giving trouble, as they are a good barrier to the extension of the infection. In stones in the common duct we locate the stone without too much exposure and, following the suggestion of Dr. Elliott of Boston, place a suture in the duct each side of the stone, using it like a stocking ball in darning. This gives control of the duct and also by tying across acts as sutures. Davis of Birmingham first called attention to the necessity of drainage of the hepatic ducts. This is very important. These cases sometimes die from lack of free drainage from the liver. The drains should be tied in place with catgut, causing it to remain *in situ* until adhesions take place, otherwise they become displaced.

DR. W. E. B. DAVIS, Birmingham, Ala.—Dr. Ferguson has referred to the operation—hepatotomy—which I have recommended in a class of cases of biliary obstruction. As stated in my paper on this subject, the operation is indicated in cases of obstruction with enlarged liver, where the gall bladder or ducts can not be isolated, or the patient's condition from exhaustion and cholemia will not permit of a protracted search for the bladder or ducts. It will be only exceptionally called for and the cases will be fewer as the surgeon's experience increases in choledochus operations as he will then be enabled to better locate the bladder and ducts so much changed by inflammatory processes. After the patient has been relieved of cholemia by the escape of bile from the incision in the liver, an operation with less danger may be done for the removal of the obstruction in the duct. In addition to the above indications I think the operation should be resorted to in hepatitis before it has reached the stage of pus formation, if the liver does not rapidly become smaller after drainage of the biliary reservoir or the ducts. My attention was first attracted to the value of the procedure in a case in which the amount of pus removed was not more than one-half ounce, but in which the division of the biliary canals resulted in the escape of large quantities of bile for many weeks.

DR. JAMES E. MOORE, Minneapolis—We are still interested in all cases that are not very well understood and in the diagnosis of those in which the cause is obscure. We can naturally make parallels between stones in the gall bladder and stones in the bladder. Recently I heard some very interesting points bearing on this condition, and it was suggested that in Minnesota there must be some climatic cause for gallstones, as there were so many operations, but the truth is that a diagnosis is made. Local tenderness is a prominent feature, and we should lay great stress on this. Dr. Robson pays great attention to this point, and the Mayo Robson point should be as familiar to us as the McBurney point. I have one interesting experience in the matter of pain as a diagnostic feature. A

8. Southern Surgical and Gynecological Transactions, vol. xiv, p. 246.

man 35 years of age had repeated attacks of pain about 2 o'clock in the morning. The pain was excruciating and was accompanied by vomiting. If he would lie down on his left side a tumor appeared in the median line. I made a median incision and found a large gall bladder full of stones with abundant adhesions. I removed the gall bladder through this incision. As to the attachment of the gall bladder at the upper end of the wound, Dr. Ferguson says this should always be done in order to avoid a sinus, but I think this depends on the size of the liver. I remember one case where it could not have been done on account of the right lobe of the liver coming so low, so that there are exceptions to this statement. I fastened the gall bladder low down in this case and no sinus resulted. I am sure that a sinus depends on the manner in which the gall bladder is attached to the abdominal wall and not to the location.

DR. DUDLEY P. ALLEN, Cleveland, Ohio—Two years ago I had, during a period of about five weeks' practice, five cases of suppuration of the gall bladder. That cases of this kind occur frequently and are so serious when they do occur, is a strong argument in favor of early operation. Not only are cases of acute suppuration serious, but also those in which there has been long-continued inflammation so that all of the tissues surrounding the gall bladder and ducts are firmly united to them by inflammatory adhesions. On the other hand, inflammatory conditions of the gall bladder, whether associated with stones or not, if taken early are usually operated on without serious risk. Beside, there are many cases in which there are indefinite symptoms of distress in the epigastrium, often long continued, and sometimes supposed to be due to malignant disease, which on exploration are found to be due to the presence of gallstones. In a very considerable number of such cases I have found on exploration conditions which could be entirely relieved. Frequently gallstones exist for a long period, and although they do not give the classical symptoms of jaundice, colic and vomiting, they still may cause grave disturbances of digestion and depression of the general health. I would strongly urge, therefore, the importance of exploration in cases where the symptoms point toward difficulty in the region of the epigastrium, even although a positive diagnosis can not be made. The dangers of an exploration are slight; the chances of benefit have, in my experience, been far in excess of what I could have anticipated and inasmuch as late operations are beset with greatly-increased severity and danger to life it would seem to me that we are warranted in taking a strong position in favor of early exploration.

DR. JOSEPH RANSOHOFF, Cincinnati—As to the diagnosis of gallstones, we often operate on the kidney and find nothing wrong, but this does not often happen with the gall bladder. We have no single positive symptom indicative of gallstones, and yet there is something about a case in which we suspect gallstones that, when operated on, will certainly show something. If there is nothing in the upper portion that is positive, particularly where the symptoms are especially developed on the part of the stomach itself, it is probably safe to come to the conclusion that there is something wrong with the gall bladder. As to recurrences, secondary operations have had to be done in some cases, but as to whether there had been a recurrence of the gallstones is an interesting question. Years ago I read a paper on this subject. I then said, and say now, that almost all gallstones that one finds in the gall bladder are nearly alike in shape and size; everything seemed to indicate that they were formed at one and the same time. If we do have to operate a second time it is usually because one or more stones have been overlooked. We occasionally promise our patients, where their gall bladder is emptied, that they will be freed from their disease, and as we are reasonably certain the operation has been complete, there is but little danger of a return of the condition.

DR. R. H. GIBBONS, Scranton, Pa.—Dr. McBurney did not offer the operation through the duodenum as a matter of choice, but as a matter of election. It is only when the stone is low down in the common duct next to the intestinal wall that he recommends it. This operation, transduodenal, was given to the profession only after thorough trial by McBurney himself, as has been given all the other surgical procedures of this not only distinguished but remarkable surgeon. The place that he has given to the method it still maintains, and in no other route can a stone, situated low down in the duct, in the ampulla, be removed by so easy, hence safe, a method as by this. The one great danger, it seems to me, in dealing with a stone low down in the duct, is injury to the duct of Wirsung, which is now looked on as being the chief cause of hemorrhagic pancreatitis. In what safer way can we keep from injuring this important territory, the ampulla, where the duct of Wirsung empties through its mouth, than by this cleverly-designed operation of one of our great American surgeons, the transduodenal operation for stone in the common duct, or, more strictly speaking, McBurney's operation for gallstones?

DR. MILES F. PORTER, Ft. Wayne, Ind.—The place at which the gall bladder is attached is not so important as is the manner of its attachment. The manner and not the location is important. Pull it out and stitch it to the skin and you will have a fistula for a long time. Stitch the gall bladder to the peritoneum only and the fistula will soon close.

DR. ROBERT F. WEIR, New York—I am in accord with those who have advocated leaving the wound of the common duct open and not sewing it up. Let it drain and supplement the drainage by the use of Cathcart's or Dawbarn's apparatus. I use a large glass tube through the abdominal wound down to the wound in the common duct, and in this a smaller tube is carried, through which siphon suction, if used, is resorted to. Another point is that in some cases where we have not been able to determine previously whether the common duct is patent or not, or when you have operated on a case where you have found a stone in the gall bladder and you do not know whether there is another blocking up the passage, I resort to a little method of my own. At the closure of the opening, when the gall bladder has been fastened to the peritoneum and just before the drainage tube has been put in position, which I secure with a purse-string suture, I place a small pellet of methylene blue into the gall bladder. If the tube is patent it will escape promptly into the intestines and color the feces, and this doubtful point will then be settled.

DR. HENRY O. MARCY, Boston—I disagree with one of the speakers, who said that this question is comparatively a settled one, as the conditions are always questionable until the abdomen is opened. We should make our diagnosis sufficiently correct to warrant an exploratory operation, and then be governed by the conditions actually existing. I believe that a large share of these doubtful cases, such as come to the majority of us, are of neglected conditions, due to unwarranted delay. If we operate early everything gives promise of an easy cure. I am glad to feel that I am growing more and more enthusiastic in reference to the surgery of the gall bladder, and yet the last case on which I operated a few days since died. The pathology seems to show that it was simply an obstructed duct from a paralyzed and dilated gall bladder without any calculi. The gall bladder was extremely dilated and filled with very thick bile, the duct being patent. The woman died from cholemia. It was easy to determine that we had a patent duct, but the cholemic conditions were so marked and the operation had been so long delayed, because it was thought to be cancer, that the end was fatal.

DR. FERGUSON—I have three cases where the gall bladder was sutured to the abdominal wall at the lower angle of the wound and three fistulas followed, one in Johns Hopkins, one in Cincinnati, and one in Chicago. The gall bladder should always be attached to the upper angle of the wound, as this will enable us to drain while the patient is lying down. I never saw a case of recurrent gallstones. I had one sent to me as being such a thing, but it turned out to be a large roll of silk used in the operation. I have operated on the gall bladder and found no stones. Colic had been very severe, and was due in two of the cases to flexion of the gall bladder, it being downward and inward. Overdistension occurred, as it could not empty itself. By fastening it to its proper place the patients were cured. I believe in draining every gall bladder I open, so that it may

contract down and act as a tube draining the liver. I do not condemn cholecystectomy when it is indicated, but I believe in leaving the gall bladder there when you can, as it will act as a drainage tube.

Suturing of the common duct I have practically discarded, as it prolongs the operation, and you do not get the proper drainage. If you have infection present and you suture, you do a bad piece of surgery. The very cases where you can suture the common duct are those where the bile is sterile, and in all these cases it is necessary to drain. I use the Packard string in my operations, and it has fulfilled all the indications for me. I would like to say a word about the severe cases. You have all the clinical evidence of fulminating appendicitis and perforative appendicitis. These cases should be operated on instantly.

VENEREAL PROPHYLAXIS THAT IS FEASIBLE.*

LUDWIG WEISS, M.D.
Attending Physician to the Skin and Genito-Urinary Department of the German Poliklinik, Consulting Dermatologist Hebrew Orphan Asylum.
NEW YORK CITY.

In attempting to speak on the prophylaxis of venereal diseases before so highly a representative body, the reader is conscious of the fact that he has only very little to offer that is new and that has not already engaged the minds of his peers assembled here. The topic is of vast importance to the well-being of the people, whose working and earning capacity is encroached on, not so much by the active accidents caused by those diseases, but much more through their chronic manifestations, especially in women. My object is that the profession as a whole should take cognizance of this ever-present scourge and its dangers to society, through the medium of the American Medical Association, and that a propaganda of action should be instituted by the members in their different states to devise measures for diminishing the spread of and for reducing the morbidity and mortality from venereal diseases.

In New York City we had occasion to witness two efforts within two years dealing with this question. The one emanated from representative and public-spirited citizens forming a Committee of Fifteen, to institute a search of inquiry into the causes of prostitution, especially in the tenement houses. This wave of reform stirred the medical profession from its latent endeavor into action, and as a result the President of the Medical Society of the County of New York, in pursuance of a resolution adopted by the society Feb. 25, 1901, appointed a Committee of Seven for the "study of measures for the prophylaxis of venereal diseases."

The able report of its chairman, Dr. Prince A. Morrow, has no doubt been perused by you. The writer enjoyed the privilege of serving as secretary to the committee and of analyzing and classifying the returns which came as answers to the circular letter sent to the profession of Greater New York. He is therefore somewhat acquainted with the ideas held by the profession here on this topic.

In attempting to deal with the prophylaxis of venereal diseases I am well aware that I am dangerously near to a very delicate topic, prostitution, and that I am running the risk of becoming engaged in the maelstrom of arguments for and against its reglementation, its segregation or its tacit toleration, and of an array of opinions which have been recommended and condemned by their exponents in good faith. At the same time, I would have to take issue with the state authorities for their inaction in reference to our topic and for their neglect to take notice of a class of diseases which inflicts severer misfortune to the population than all other scourges together.

I would have to cross arms with those Utopian moralists who interfere with every attempt of sanitary intervention in venereal diseases, by their sincere but bigoted hyper-puritanism and utterly misdirected efforts of trying to change human nature under the prevailing socio-economic conditions. Let me emphasize in anticipation of the following that the reader, as well as every one of us, no doubt, would hail with delight that advent of the expected millenium when the moral sense of humanity will have developed into that sublime conception of purity of thought and action which looks on the consummation of marital relations as the solemnized and only legitimate means of satisfying physical love for purposes of mutuality and procreation.

But if we study the natural history of mankind from its primeval states of herding of clan and kinships up to the foundation of orderly communities, under self-imposed restrictive laws, we find that the individual who renounced his rights for the good of the common weal, reserved polygamy, of which he would not suffer himself to be deprived. With the dawn of civilization the innate sense of jealousy became more conscious in men, developing in them the desire for possession, and urging them on toward polygamy. But the very same moral shortcomings gradually paved the way towards monogamy also. It was now the ardent desire for sole possession engendered by the nobler traits physiologically inherent in the female which appealed to the awakening moral sense of man.

Christianity fostered these sentiments and monogamy became the status of all civilized peoples. However, by the law of atavism, an occasional retroverting into the barbaric state of remote ages, a dormant inclination or propensity towards polygamy is dimly extant in man. This defect must be looked on as a physiologic weakness. These polygamic proclivities, attenuated as they are by the influence of religion, education and science, and through the monogamic conditions of many thousand years, are not as yet entirely eradicated in man.

Women possess a higher sense of morals, developed in them through ages by the physiologic process of child-bearing, engendering in them that supreme motherly love, limitless self-denial and readiness for sacrifice which we all admire so much. In women polyandric tendencies are almost extinct, as a rule. If present, such atavism is of infinitesimal proportion and a factor well-nigh negligible.

In those rare instances where such atavism in women manifests itself in a marked degree we are justified to see stigmata of degeneration, caused probably by the presence of aberrant cell formations in the brain of primeval origin. A life of vice in women indicates therefore a deeper downfall and a retroverting into primitive conditions out of which Nature has elevated her.[1] If we add to these atavistic abnormalities the influence of adverse socio-economic conditions, we will at once perceive how such tainted characters of lesser value might succumb, producing as a type a fallen woman. The evolution of prostitution therefore is a biologic as well as a social phenomenon.

While the above views are in line with those held by such authorities as Lombroso and Tarnowsky, there are

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. W. T. Corlett, L. Duncan Bulkley and W. L. Baum.

others who attribute to this theory of evolution some, but not the main, importance. It is held by them that the prostitute is in the main the outgrowth of environment, of socio-economic conditions and of the sexual hyperactivity of man. Be that as it may, prostitution must be regarded as the fountain head from which venereal diseases originate. It forms the main source from, through and toward which courses in an unbroken vitiated stream the poison which inoculates the living and contaminates those yet unborn. In comparison to this, all other modes of propagation are *nil.* In order to stamp out venereal diseases absolutely prostitution must be annihilated first. No prostitution, no venereal diseases. To prevent them some measures must be instituted against it. Any prophylaxis instituted against their spread must necessarily begin with measures directed toward either the suppression or repression of prostitution.

SUPPRESSION.

But since prostitution *can not be suppressed,* and history shows that it resisted every onslaught, it should not, but it must be regarded as an inevitable evil, a phenomenon as old as the legends and the history of humankind itself; and so long as man must be defined as an "intellectual being limited by sensuality," so long will the absolute "crucifixion of the flesh" be an impossibility, contrary to the spiritual perceptions of the dominant mind.

REPRESSION OR REGLEMENTATION.

The sanitary supervision by reglementation of prostitution endeavors to influence the inevitable evil, by searching for diseased prostitutes and subjecting them to police surveillance and compulsory hospital treatment when diseased. While such measures would in a way undoubtedly diminish the sources of contagion, yet the vastly larger number of the yet more dangerous unregistered clandestine prostitutes would remain exempt from its provisions. Furthermore, registration carried out with thoroughness will, in order to escape degrading sanitary police measures, invariably diminish the number of public prostitutes and augment the ranks of the clandestine ones. Regulation of any kind, at first glance so easy and seductive, is in reality one of the most complicated problems with which the best elements of continental countries have tried in vain to cope. Paris has a century of unsuccessful experience with it. It always strikes home and jeopardizes the very condition for the relief of which it was created.

Besides, the registering of prostitutes, so alien to the American idea of consideration even toward fallen women, meets, as it did in St. Louis in 1872, with an abhorrence of public sentiment against legal recognition of vice. But besides sentimental notions there are, as stated before, more valid reasons which complicate the question.

In the social order of to-day so many factors converge in the make-up of this complex question—constitutional rights, restriction of personal liberty, infringement of private rights, moral considerations, and so forth—that reglementation proved futile and suppression a Utopian idea. While looking on prostitution as a vice, and not as a crime, the punishment of which is not strictly within the province of the government, prostitution will, when regarded with a sense of tacit toleration, work out its own destiny. As the law forbids the existence of any disorderly house in tenements or within a certain radius of a school, a church or a young men's club, such resorts will, with their well-known tendencies of aggregation, occupy less conspicuous quarters, and a natural self-evolved segregation will take place, excluding police interference and blackmail, with a possibility of better sanitary conditions. Furthermore, laws should be enacted for the suppression of quacks and dispensing druggists. Sick-benefit societies should be compelled not to exclude, as they do now, diseased venereal members from the benefits granted by such organizations.

SOCIAL, ECONOMIC AND LEGISLATIVE MEASURES.

The entrance of women into self-supporting industrial life has surrounded her with dangers, against which she must yet develop defensive measures; but it is the duty of the state to lend her a helping hand to cope with a new condition. To this end the existing labor laws (mercantile and factory laws) must contain some new provisions, such as the minimum rate of wages for female employes over 16 years of age shall not be less than a sum sufficient to keep such a person in food and clothing according to the prevailing social conditions to which such an employe is reasonably entitled. Division of the sexes in workshops. Working women's and men's compulsory sick-benefit, accident, invalid and old age insurance societies and mutual aid and loan associations for industrial workers, to tide them over in time of non-employment. Asylums where friendless working women could find accommodations at nominal rates, or where in temporary embarrassment or if out of work they could be accommodated gratuitously in lieu of some work exacted from them, such benefit to be accorded only on recommendation of a charity organization society. Better housing facilities,[2] shorter working hours, extension of the eight-hour law as constituting a day's work. In addition, industrial schools, cooking and servants' schools should be established.

A provident educational law,[3] like the one introduced in Prussia in 1900, should be created, which endeavors to minimize the dangers to minors, putting those of evil propensities under responsible guardianship until they have reached their twenty-first year.

EDUCATION.

Education is the most potent of all factors and the most difficult to yield immediate results. A campaign of education instituted along all social lines will bear fruit slowly but surely. For those of both sexes whose schooling terminates on entering into industrial life—in New York the fourteenth year—evening reading classes, lectures on sexual hygiene, on abuse of alcohol, etc., should be furnished by the board of education and delivered by school physicians of the respective sexes.

Trade schools with gratuitous instruction and labor employment offices connected with the above-mentioned asylums should be founded. Respect for women, such a great factor to enhance purity of thought and action and to promote self-restraint, is sadly neglected nowadays; this is due to the promiscuous intermingling of sexes in industrial life. There is a tendency in the male element of losing its chivalry towards a female since the latter has entered into competition with him. This is one of the unforeseen stages in the evolutions of character, a symptom of new conditions.

For both sexes whose curriculum of education extends to high schools and colleges, a course of obligatory lectures delivered by teachers of their respective sexes and dealing with the dangers of venereal disease with rare tact and delicacy, will prove a great educational factor for disseminating a necessary knowledge of nonprurient character. Physicians, as the sanitary counselors of families, can find a promising field for ex-

plaining and teaching on these delicate topics, when parents would feel a natural reluctance of proceeding. As a thorough education of the medical profession on the topic of venerology is one of the greatest allies for combating venereal diseases, students should be given a broader instruction in venerology. It should be included in the curriculum as compulsory, and a rigorous examination required as an essential requisite for obtaining a diploma.

As a step in the right direction must be regarded the delivering of lectures at the German universities, in which students are recommended to lead a chaste life and impressed with the dangers of sexual diseases and of the intercourse with prostitutes, and that continency is perfectly compatible with health. Eminent professors have issued a warning appeal to the students, which is handed to them at the time of the matriculation and otherwise distributed broadcast and given a place on the bulletin boards.

As police regulations have proven irksome and unpromising,[4] and continental sanitary regulations do not yield the results expected from them, we must try to reach the point of advantage by a rather indirect road. Measures almost paternal in their conceptions are the somewhat circuitous but safest routes to accomplish something. Results will not show at once—it took ages to develop what we have, and only succeeding generations will harvest the fruits of our labors—but commence we must, even if the liberty of some individuals is encroached on. I declare most emphatically that the state can not afford to neglect to take cognizance of the plague with impunity, and that between the unwholesome conflict of sanitary and moral interests we have found that morality is in no way increasing by relegating the sanitary aspect of the question to the background.

Some state legislation, not necessarily reglementation, is needed, and constitutional objections will have to be removed by previous amendments. The law, however, should interfere where vice exhibits itself in a shameless and provocative manner in streets, low resorts and shows; it should suppress low-grade sheets devoted to the exploitation by word and lascivious illustrations of scandalous gossip and glorification of adventuresses and the demimonde.

According to Blaschko,[5] of 573 unmarried syphilitic men the source of infection could be traced in 487 instances, i. e., in 81 per cent., to prostitution. In Fournier's 873 cases of syphilis, 671, or 77 per cent., were due to prostitution. In St. Petersburg, Tschikchajeff found that out of 500 cases of venereal diseases 73 per cent. could be traced to prostitution. In Budapest 85 per cent., in Braila (Roumania) 80 per cent. of all venereal diseases were due to the same source. It has been found by Hammer in Stuttgart that every prostitute becomes infected with gonorrhea at least once in a year, and that according to Blaschko one-third to one-half of all prostitutes of Berlin are continually afflicted with gonorrhea. Jadassohn in Berne came to the same conclusion. Sperk in St. Petersburg found 83 per cent. of all prostitutes syphilitic after the first year. Schulz, Budapest, found 65 per cent. infected with gonorrhea. Neisser found that in Breslau of 572 prostitutes 217 had gonorrhea. Blaschko found that two-thirds of 200 males get their syphilis from public, one-third from clandestine, prostitutes. There are, according to the same authorities, 150,000 syphilitics in Berlin, or 12 per cent. of the inhabitants; in Paris, according to Le Noir and Fournier, from 13 to 18 per cent.; in Copenhagen one of every 55 young men of the age between 20 and 30 has syphilis and one in 8 has gonorrhea. In the city of New York Morrow[6] estimates the number to reach 200,000. The same ratio holds good with very little oscillations in every capital or large city.

In their returns to the circular letter sent out by the Committee of Seven of the Medical Society of the County of New York, 678 physicians reported 23,196 cases of venereal diseases, of which 11,968 were traceable to prostitution. Among a student body of 600 in Berlin belonging to a sick-benefit association, Blaschko found 25 per cent., Neisser in Breslau 10 per cent., Strohmberg in Dorpat 24 per cent. afflicted with syphilis; all students of the latter town, however, had had gonorrhea traceable to prostitution.

These numbers could be multiplied infinitely, but enough has been shown to convince any one open to conviction that we have to look on prostitution as the main causative factor for the spread of venereal diseases. The moral regulation of vice presupposes an adaptability of the human character to lofty ethical requirements, to which the inherited taint of ages and the reigning socio-economic conditions have ill-fitted it. It is true that prostitution poisons both mind and body, but it is not clear why the physical aspect of its consequences should be treated as a secondary consideration. The endeavor of the moralist to regulate vice by exclusively ethical means is a too rigid adherence to abstract reasoning, the results of which are slow of materializing. The present status of things needs a quicker remedy. Moralists and sanitarians must meet by mutual concessions on a common platform. There are good points in each system, but better ones yet in a blending of both.

It is in this sense that we must hail with delight the excellent report of the Committee of Fifteen of New York,[7] in which men of the highest standing in the community and of unimpeachable character recommend for the first time sanitary steps also. While not recommending sanitary regulation *per se,* it voices the necessity of increased hospital facilities for those afflicted with venereal diseases, and in recommending so-called moral regulation of vice, it does not entertain the delusive hope of seeing human nature changing in a single generation, but with the ultimate end of moral redemption from the degrading evil. This deviation from the inflexible standpoint of the moralist, with his adage, "Let them rot in their own vices," so alien to the teachings of the highest humanity, will imbue the sanitarian with hopes that a mutual understanding is possible. Until such combined efforts will meet the realization we must try to add to our armamentarium any measures that have proved efficacious in preventing venereal diseases.

And this brings me to the consideration of individual prophylaxis, which, under the present conditions, is the nearest measure available.

GENERAL INDIVIDUAL PROPHYLAXIS.

The danger of acquiring syphilis or ulcus molle is a remoter one than that of gonorrhea. Its contagion not being perfectly known, neutralizing agents could not as yet be devised. Until science places at our disposal an immunizing and healing agent like Behring's diphtheria antitoxin, we are compelled to utilize the meager results of clinical experience.

It seems as if circumcision would diminish somewhat the chances of acquiring syphilis. The statistics given by Joseph and Hutchinson must be taken, as they themselves guardedly say, with precaution. But future sta-

tistics on this topic might prove of interest.[8] I may be permitted to allude here to the dangers of ritual circumcision when performed with no regard to asepsis whatever and to the possibility of transmitting syphilis. As this operation is as yet performed in a great many instances, a law permitting physicians or graduated circumcisors only to do the operation would prove to be a prophylactic step that is feasible.

The entire class of syphilis insontium, so ably dealt with by Bulkley of New York,[9] showing us the manifold routes by which extragenital lues is acquired, gives us an incentive to warn people against the most common sources of such unfortunate infections. Infection has been carried by ragged-edged drinking glasses and knives, cigar holders, cigars, the tips of which were molded between the lips of syphilitic workers; by razors, powder puffs, shaving cups, strops, towels; by dental, ear and laryngoscopic instruments; by glass-blowers' pipes; by the mouth pieces of speaking tubes and telephones; by the use of common drinking mugs and communal cups;[10] by lead pencils; by vaccination; by hypodermic needles, and by manicurists' tools. The latter class, through their indocility, are a menace to health and second only to the dirty-tooled and dirty-nailed dentists abounding unpunished among us. These economic brephotrophic and technical infections (Bulkley), every source of which can not be mentioned here, form a legitimate field for feasible prophylactic measures. Trade sanitary laws for glass blowers, barbers, manicurists, cigar makers, etc., are urgently needed. Concerning wet nurses, a medical examination of both wet nurse and infant must be made obligatory, and a law, making it a punishable offense for each party to knowingly impart syphilitic infection, must be put on the statute books. This is a truly necessary and feasible prophylactic step.

In the recent and most successful crusade against tuberculosis in New York a spitting and more recently a smoke ordinance was promulgated, which can not be too highly commended.

It is with a feeling of regret that I mention the great gulf that separates our endeavors from the community, which, like most of the states, take no interest whatever to institute a sanitary prophylaxis of venereal diseases. Tuberculosis we all know to be one of the greatest scourges that afflict humanity, but the hecatombs exacted by the sequelæ of venereal diseases in guilty and innocents alike, cry towards heaven. Certainly we do not envy the poor tuberculous patients their state and communal sanitariums, but we should like to see a modest mite come our way also, in the form of larger hospital facilities and of asylums.

SPECIAL INDIVIDUAL PROPHYLAXIS.

The aim of individual prophylaxis consists in destroying the pathogenic germ before incubation has set in. Generally, the condom is too rarely used. As to syphilis, the use of ointment has been recommended long ago as offering some protection, and lately mercurial ointment has been recommended by Behrman,[11] and P. Cohn[12] looks on it as a useful prophylactic. There is some reason to expect that it might act preventatively as a protecting film, and as a local immunizing agency by virtue of its antidotal qualities.

Acting on this principle, Richter[13] has devised a melting bougie of the formula, unguenti cinerei 40 per cent., resorcini 0.25 per cent., the tip of which is introduced into the urethra, broken off and left there to melt. He reports encouraging statistics. As to ulcus molle, caused most probably by the streptobacillus of Ducrey-Unna, general prophylactic measures, washing with permanganate solution, ointing of the membrum as before said, and in case of its appearance, excision or cauterization with pure carbolic acid are feasible prophylactics.

Gonorrhea is the only one of the trio of venereal diseases where individual prophylaxis is efficient with a promptness almost bordering on security. Its contagion being a fixed one—the gonococcus—agents for its destruction have been devised with success.

While lues can be acquired in an innocent way, gonorrhea is most closely allied to prostitution. If we could annihilate prostitution, gonorrhea would disappear. But as we can not reach that goal under the present moral evolution of the race, it is our duty to lessen the ravages of an evil which we can not inhibit, try as we may. Here we must act as sanitarians mainly, considering it moral to intercede and criminal not to prevent infection, when in the largest number of cases we are well able to do so.

We know that about 80 per cent. of all men have had gonorrhea once or several times; that gonorrhea is not only a local but in many instances a systemic disease, attacking almost every structure, as pointed out by Bernutz in 1857,[14] and especially by Noeggerrath in 1872,[15] and the causative factor—especially in its latent form—of the most severe kind of pelvic diseases in women, produced by the gonococcus or its toxins.[16] It causes sterility in both sexes,[17] ophthalmogonorrhea[18] and blindness in the new born, and often mutilation of the female generative organs. Gonorrhea being most obstinate of curing—the modern one-minute cures notwithstanding—usually leaves behind more or less extended structural changes of the urethra, its follicular apparatus, or the accessory glands. The dangers to health and to the capacity for work and earning are greater than that of syphilis.

The proportion of gonorrhea to other venereal diseases is, according to Neisser, 47.3 per cent. of the whole number, according to Blaschko 70 per cent., syphilis representing respectively 42.4 and 22 per cent., and soft chancre respectively 10.4 and 8 per cent. This cursory allusion to the social danger of gonorrhea is sufficient cause for advising individual prophylaxis that has proven both successful and feasible.

It is, to my knowledge, the first time that the topic of personal prophylaxis has been brought before an American Medical Association audience, and it is with a feeling of reluctance that I try to interest you in this branch of preventative medicine. You may feel assured to find yourself in harmony with the best authorities of our branch and in enviably good company. Let me quote some references to this end and in a casual way. According to Neisser 50 per cent. of all involuntary childless marriages are due to gonorrhea of the female genital organs, of which at least 45 per cent. are due to gonorrheas of the men. Kehrer found that in 96 sterile marriages 33 per cent. were due to perimetritic exudations, 30 per cent. to azoöspermia after gonorrhea, and in 227 women Lier and Asch found 121 sterile in consequence of gonorrhea. Greenwald, Kammerer and Chroback report 53, 83 and 40 per cent. of metrides, all of gonorrheic origin causing sterility.

Ten to 20 per cent. of all blindness is due to gonorrheal infection of the new born; from 40 to 60 per cent. before the Credé method was instituted.

Prof. A. Neisser, the discoverer of the gonococcus, in a paper,[19] "Attempts to Avoid Gonorrheic Urethral In-

fection," read before the Silesian Society for Home Culture, March 15, 1895, recommends instillations into the urethra, similar to Credé's, introduced by Blokusewski to check the enormous propagation of gonorrhea. He says:

I know that such endeavors emanating from physicians will be condemned by others who are of the opinion that fear of infection might be conducive of diminishing the frequency of intercourse in young men. . . . Even he, who looks on moral influence as the main prophylactic agency against venereal diseases, must stop to think that gonorrhea is not a simple, troublesome or painful affection passing quickly, but that in many cases it proves to be the source of a severe, tedious sickness for innocence. If we could familiarize this prophylactic method with the "interested circles" surely countless infections would be nipped in the bud, countless gonorrheas could be prevented.

At the Conference for the Prophylaxis of Syphilis and Venereal Diseases, held at Brussels, September, 1899, Neisser again convincingly pleaded for the most extended use of these prophylactic instillations.

Lederman[20] says:

Great credit is due to Neisser for having recommended these measures. . . . I am ready with all my powers to work for a most extensive use of these prophylactic instillations.

Ernest R. W. Frank,[21] Berlin, in a paper read before the Sixth Congress of the German Dermatologic Society, says on this topic:

He who comes before the public with a proposition trying to prevent venereal diseases by some preventative remedy will not escape a conflict with those moralists who see a moral coercion in the fear for infection. This aim is very distant from the standpoint occupied by the physician and hygienist.

Prof. M. Zeissl,[22] Vienna, says:

Since innocents are also threatened, it is desirable to counteract energetically the spread of gonorrhea and to prevent the possibility of a man acquiring gonorrhea at all. There is no doubt that the safest and most moral means to attain this end is the avoidance of illegitimate intercourse. But this is a pium desideratum, the fulfillment of which will hardly ever come to pass. . . . It would be desirable if the method of Frank (protargol instillations) would come into general use. . . . I believe that, in view of the safety of this method, it is the duty of every physician to recommend its use.

Prof. C. Kopp,[23] Munich, says:

I would emphasize that the interested parties should make use of the prophylacticum in every instance. The measure speaks well as regards its efficacy and safety.

Prof. Th. Marschalko,[24] Klausenberg, in a paper read before the Royal Hungarian Medical Society, Budapest, January, 1901, says:

I regard the general use of prophylactic instillations as the only means to limit with success the enormous spread of gonorrhea.

Max Joseph, Berlin, in reply to an inquiry from the reader, writes thus:

Your inquiry as regards prophylaxis is, as you yourself state, difficult to answer. One thing is sure, state prophylaxis has proven very inefficient. I think we must rather rely on personal prophylaxis, which will undoubtedly be the future ideal. What can be attained by it you will find in the May number of my *Centralblatt*. I believe that no kind of state prophylaxis can show such favorable results.

Other continental authorities hold the same views. American authorities whom I have interviewed speak favorably of it and encourage individual prophylaxis in their clientele.

The article alluded to by Joseph is by Dr. R. Michels,[25] ship surgeon on a German steamer, showing the great efficacy of individual prophylaxis. On arrival in Yokohama 150 of the crew obtained leave of absence. Anticipating an expedition into the domain of Bacchо and Venere, and knowing that 5 per cent. of them usually returned infected, he gave each of them a vial of a 10 per cent. protargol-glycerin prophylactic for instillation and a square piece of unguentum hydrargyri, to be used before and after coitus. The result was surprising Not a single case of venereal disease developed.

To return to the individual prophylaxis of gonorrhea. The idea to employ remedies to this end did occupy the minds of generations past. Decoctions of aromatic herbs, of powdered parts of animals and other bizarre quack nostrums were recommended and sold as highly-prized secret remedies. Later on acidulated water or light potash solutions were recommended with a somewhat more valid reason. Also ointing the membrum and urinating post-coitum. In 1810 Eichhord[26] recommended the injection of diluted hydrochloric acid, and Diday constructed a small syringe for that purpose. Zeissl the elder endorsed such measures, recommending first cooling the penis by a local bath before the use of the prophylactic injection.

But a scientific preventative was possible only after the curative gonococcus was found. Haussman[27] of Berlin, in 1885, recommended the injection of ten drops of a 2 per cent. solution of nitrate of silver into the urethra; but this proved to be too irritative. Ten years later Blokusewsky,[28] acting on the principle that a 2 per cent. solution of nitrate of silver destroys the gonococcus, was the first to devise a miniature medicine dropper, enclosed in a metal cap, for the instillation into the urethra post-actum of two drops of such a solution. A third drop to be applied alongside the frenulum to eventually reach the gonococci outside in the para-urethral ducts. Although very useful and endorsed by Neisser, the silver solution through its somewhat irritating effect made its general use inhibitory.

In 1897 Ullmann[29] of Vienna, to avoid the irritating silver solution, recommended a bichlorid solution of 1 to 10,000 with the addition of bicarbonate of soda. But Welander has demonstrated that this solution does not possess any gonococcidal powers.

The eminent gonococcidal properties of protargol have appealed to Ernest R. W. Frank of Berlin in his search for a substitute for the nitrate of silver solution. He has found on the strength of irrefutable experiments that a 20 per cent. protargol-glycerin solution will also destroy gonococci within five seconds. His series of experiments were not made from gonococcus cultures, but from urethra to urethra of a microscopically determined gonorrheal discharge. All individuals experimented on remained free from infection, while those not treated with the protargol prophylactic became infected with gonorrhea.

In these preventative instillations we possess almost an exact measure to stop the development of gonorrhea, when applied early enough, i. e., immediately or within an hour after coitus. It may not succeed in every case, but even so it is a formidable weapon against the spread of the disease so troublesome in its remote effects. It should be recommended as the most feasible of all remedial prophylactics. The objections of the moralist of inciting by it licentiousness can not be entertained seriously. If the profession would entertain such sophistical reasoning it would be equally as immoral to stop the hemorrhage from an uterus containing the unexpelled secundinæ in a case of malpractice, or to apply a 2 per cent. solution of nitrate of silver in a case of ophthalmogonorrhea. In Germany, where things are called by their right names without bias, these portative

little apparatuses are publicly sold and with excellent results as to their efficacy.

The student in this country is greatly handicapped when attempting to deal with the morbidity and mortality of venereal diseases by the utter absence of statistics on this topic. The board of health in the great city of New York—and I believe this to be the case through the whole Union—controls contagious diseases with great vigor and success. Hospitals for contagious diseases of all kinds are ready to receive patients at a moment's notice, but for the housing of venereal diseases we witness a dissolving-view picture of meagerness of resources unbelievable. The vital statistics of contagious diseases hardly make mention of venereal diseases. In the year 1900 the vital statistics of the city of New York record 31,145 cases of contagious diseases in all, with 11,368 deaths, among which there are only 177 from syphilis. While the late manifestations of syphilis figure under various diagnoses regardless of their etiologic factor, gonorrhea and its sequelæ are not mentioned at all as causes of death. Venereal diseases are ignored by our sanitary authorities!

I would advise that venereal diseases be made reportable like other contagious diseases. No names and addresses need be mentioned, simply the diagnosis and source of infection should be reported by the physician for purposes of registration. This would supply an excellent if only an approximate basis to ascertain the morbidity from venereal diseases, and would prove of great utility to the sanitarian. In death returns, bound to contain names and addresses, the diagnosis of syphilis would mostly remain concealed, as is the case now; the primary or remote cause of the fatal disease could not, therefore, be made available for purposes of mortuary statistics. But registration of the morbidity alone would already mark a vast progress by elevating venereal diseases to the dignity of official recognition. Out of such a condition facts could be deduced for a feasible prophylaxis.

One of the greatest factors for diminishing the deleterious consequences of venereal diseases is the prophylaxis by treatment. It endeavors to hospitalize, isolate and treat gratuitously, as is the case in the northern countries of Europe, as many sources of contagion and as near their inception as possible. To this end a generous supply of hospital and dispensary facilities are needed. I do not encourage the erection of special hospitals. Venereal patients are very sensitive on this point, and hate to be recognized by the world as the carriers of a "shameful disease." Every hospital, especially those receiving state or municipal assistance, should have a venereal ward in proportion to its bed capacity, and their charter should contain a clause to that effect. Those already in existence must, if possible, be compelled to do so. The out-door department of every hospital should have a competent venereal service. Every dispensary should be bound to have a class for venereal diseases conducted by competent specialists. Some one of the staff should understand the necessary rudiments of the different tongues which the people in such quarters speak. In order to facilitate attendance without tell-tale loss of time to the wage-earner, evening classes should be held. Morrow relates that 70 per cent. of those admitted to the surgical night class of the New York Hospital are venereal patients.[30]

It seems that the advertising quack derives most of his ill-gotten gain by assuring perfect privacy to this class of patients. They fear keenly, as no others do, of being afflicted with a "private disease." They are very apprehensive on this point.

Venereal departments in dispensaries should be called "department for contagious diseases," or for "external diseases." ("Ausserliche Krankheiten" in Germany.) They should have separate waiting rooms for men and women. Each patient should be examined separately, unobserved by others. In my class at the German Poliklinik I have four little compartments so arranged that patients coming and going do so unseen by each other. The utmost seriousness should prevail, no cheap jokes made—there are many sinners against this injunction—and the disheartened patient made to feel, as I try to do, that he is not before his judge, but before his helper.

Morrow[31] reports the almost incredible condition that the great city of New York provides for the reception and treatment of venereal women just 26 beds, and for venereal men 56 beds in the city hospitals at Blackwell's Island. Not one women in two thousand, certainly not one man in five thousand, can obtain treatment for the active accidents of their maladies. In Berlin there are, according to Lesser, 153 beds for men and 410 for women available. In all Germany only 7 per cent. of venereal diseases are admitted. As the largest number of venereal patients are in need of ambulatory treatment only, dispensaries with venereal service should be multiplied. Morrow reports that there are only 7 dispensaries in the city of New York in which there is a venereal or genito-urinary service; ten others contain dermatologic classes where venereal diseases are also treated. Thus it will be seen how inadequate are the dispensary facilities in the city of New York as elsewhere. I presume that the same condition. if not a worse one, prevails in all larger cities of the Union.

In addition to the improved hospital and dispensary facilities a campaign of education of the patient should be instituted. Patients should be instructed by word of mouth and by the distribution of printed slips of the details of treatment and of the dangers to themselves and others.

Some moralists might see an incentive to vice in such charitable steps; not so the physician, who is imbued in no minor degree with the ideals of purity than they are, but regards even human turpitude as not outside the scope of his samaritan efforts. It would be cruel to abandon the meritorious afflicted; it would be criminal to permit innocents to suffer. To cleanse society from venereal disease we have to treat the affected ones first.

In the foregoing I have tried to outline some feasible measures for venereal prophylaxis. As some of the recommendations are of a socio-economic character, their realization will be slow to come. Our social conditions are the outgrowth of economic conditions evolved since countless centuries; and a peaceable revolution needs yet other centuries as so many stepping stones toward amending the present social iniquities. I have studiously avoided, taking in account the present moral evolution of the race, to ventilate Utopian ideas. In voicing individual prophylaxis I was conscious of its probable moral shortcomings. But while moral sterilization may save future generations, it behooves sanitarians to be mindful of the sources of acquisition of disease, for the sake of those innocents that are exposed through marital relations, for the sake of those that are deformed and lost before birth, and for the sake of those born tainted and with the curse of spreading misery in their veins.

CONCLUSIONS.

Prostitution is the main source for venereal diseases. Its suppression during the present moral evolution of the race is impossible.

Moral regulation of vice solely is a desirable ideal, but impossible of realization.

Reglementation as practiced in continental countries is impracticable here on constitutional grounds and on the ground of its limited hygienic value.

Moral efforts (social, economic, educative and legislative) combined with sanitary measures are promising of results.

As sanitary efforts under existing circumstances can step in only after infection has already taken place, a liberal supply of hospitals and dispensaries with free treatment must be provided for purposes of treating and sterilizing sources of contagion.

Individual prophylaxis is at present the only feasible means of preventing in part the spread of venereal diseases.

It is the duty of every physician to recommend it.

The Section on Cutaneous Medicine and Surgery of the American Medical Association should strive to bring about a uniform nomenclature, and the Association should institute through this Section a propaganda of action in the different states; to bring about under its auspices a national meeting similar to the International Conference for the Prophylaxis of Venereal Diseases which meets again this year in Brussels.

DISCUSSION.

DR. A. D. MEWBORN, New York—I would like to suggest one point in regard to the statistical duplication of venereal diseases or other diseases attributable to venereal origin, and that is that the dispensaries and hospitals should make an annual report so that the profession and public could be educated to know the extent to which those diseases exist. I think the Section should take action in adopting a uniform nomenclature, and I think the nomenclature of Bertillon would be desirable instead of X and 3X and all sorts of hidden devices which tend to make the matter secret. The hospital and dispensary reports should show the extent to which those diseases exist.

DR. C. W. ALLEN, New York—I think this is a most important subject. There has been a great deal of work done in this direction in foreign countries and some has been done here. I think the New York County Medical Society has made an honest effort to do something. I did not think when the Committee of Seven was appointed to carry out the investigation mentioned that it would amount to very much and so expressed myself. I based my opinion on efforts which had been made in the past. It takes years and years to get anything done in this particular field. The public never seems to be ready for it, never seems to be willing to act on any suggestion coming from medical men, but I think such papers as we have listened to should continue to be written, suggestions should continue to be made, and the time will come when some useful measures will be adopted toward the prophylaxis of venereal disease.

DR. E. L. COCKS, New York—Dr. Allen has struck the keynote of the situation. It has been my experience that all writers treat this disease too lightly and why they do I do not understand. It is a disease that has always existed, and always will, and if instead of looking up statistics we will appoint ourselves a committee of one, and as a general practitioner take the father in hand, and if he has not the courage of his convictions, then the son, tell him what is before him, we will accomplish a great deal toward the desired end. The prophylaxis that Dr. Weiss has presented here is all very well, but I would not put it into the hands of any man. The whole trouble has been, especially in New York, that the physicians, and more especially the ministers, periodically have a streak of over-conscientiousness and try to do something, and the result has been, so far as the other part of New York City is concerned, that prostitution, which was confined to Dr. Allen's neighborhood, viz., the tenderloin, has been scattered all over the city. Everyone knew that when a young man entered this territory he had but one object in view, and this knowledge caused many a man to hesitate, then turn back. Under the new order of things prostitutes are now our neighbors, and the above barrier to indulgence has been removed. All the legislation in the wide world will not do one particle of good, but heart-to-heart talks will. I do not know whether it is simply my experience, but it seems that the advice given by physicians in New York City when a young man has had one or more nocturnal emissions is to advise him to gratify his sexual appetite. One case I have in mind now of a young fellow only sixteen who was given that advice, and three weeks later he came to me with a chancre. What I want you to do is to appoint yourselves a committee of one and give the advice that we know ought to be given, either to the parents or to the young men themselves, and by so doing I think we can to some extent eradicate the evil. Where there is a demand for sexual intercourse it will be met,

and if by our advice we can cut down the demand the supply will diminish.

DR. W. S. GOTTHEIL, New York—I am sure that we are all very much obliged to Dr. Weiss for presenting this subject. The venereal portion of our dermatologic "disciplin," as the Germans would say, has been rather neglected in the past; and I assume that we are all desirous to limit the spread of venereal disease, and must therefore agree in the main with most of what the writer has said. We must not forget, however, that we always have had, always will have, and always must have prostitution in one form or another; and that, whatever the moralists may tell us, history and common sense show it to be a social necessity. It is a mistake to regard the prostitute as a criminal, and to adopt exceptional measures against her as such. Her calling is socially undesirable, and would have no place in an ideal society. But the same can be said of gambling, which in many places is regarded as a legitimate occupation; and there are entirely proper business occupations that can only with difficulty be differentiated from gambling. I am firmly of the opinion that the English method of dealing with the social evil is the proper one, and that municipal regulation, as practiced in many European cities, is neither successful nor desirable. It must be tolerated like many other necessary evils, and should be interfered with only when police reasons for such a course exist. I am in accord with Dr. Weiss as to individual prophylaxis, but that is a matter that lies with the patient and his physician.

DR. F. H. MONTGOMERY, Chicago—We must all, even those of us most strongly opposed to some of the measures advocated in this paper, recognize the courage—evidently born of conviction—and the great care with which Dr. Weiss has presented this subject. His suggestions regarding the regulation of tenement houses, stores and factories are exceedingly valuable and important. Few who have not studied the situation realize to what extent in some of our large cities the reputable poor of all ages are compelled to associate, not only in their work, but also in their homes, with those who make crime and sin their means of livelihood.

The measures of individual prophylaxis recommended by Dr. Weiss should be unqualifiedly condemned. They are wholly wrong in principle and opposed to the progress we wish to make along educational lines; and, moreover, I believe their use would lead eventually to an increase rather than a diminution of venereal disease. The average man who exposes himself to venereal disease is going to exercise much less self-control and expose himself much more frequently if he thinks he is armed with a means of protecting himself. That the protection afforded by these measures is not complete, but only partial and more or less uncertain, must be admitted by their most ardent advocates.

I agree fully with one of the previous speakers in believing that the prevention of venereal diseases must be accomplished very largely through the proper education of the young. It is a sad fact that practicing physicians are found not infrequently who have never been educated properly along these lines, and whose advice to young men is often pernicious if not criminal.

DR. H. G. ANTHONY, Chicago—I think one of the ways to solve this problem is through education. Young boys I find have ideas in regard to venereal diseases and the sexual organs, which they obtain from comrades and coachmen; it is far better to have them listen to intelligent lectures in universities and colleges and let them get an intelligent idea of venereal diseases, their dangers and the difficulty of prophylaxis. In this way I think a great deal can be accomplished to limit the spread of venereal diseases. Another thing of great importance, when a man has once contracted gonorrhea he thinks when the discharge ceases he is entirely well, while we know that for a long time the gonococcus is contained in the urethra and is a source of infection, and that should be pointed out by the physician and the danger of infection of women while the gonococcus is present. I think these antiseptic measures are harmful. When a physician places such things in the hands of a young man he thinks he is safe when he is not. You can not prevent the contagion of syphilis by any such means as these antiseptic solutions. Just as soon as the syphilitic virus touches a surface we know that infection takes place. Neither do I believe that any of these various means will prevent gonorrhea. I think if the gonococcus is present in the vagina of the woman and comes in contact with the mucous surface these antiseptic means are not sufficient to prevent contagion.

DR. DAVID LIEBERTHAL, Chicago—Four years ago I wrote a paper on this subject, and I find myself in general agreement with the views of Dr. Weiss. The statistics quoted seem to be plausible, although they may be unreliable, as are a good many other statistics. It seems at least probable that a far larger percentage of infections originates from other sources than from prostitutes. The suggestions offered by Dr. Weiss are to the point, although some can not easily be carried out. Especially the question of educating the young in this direction is very well worth considering, even admitting that religious objections might frequently prevent it. I recollect a conversation with a gentleman leading up to this topic, who said he would not permit anybody to mention such a subject to his boy, and this boy was 21, and there are thousands of people similarly disposed. What seems to be of greater importance is the necessity of well-equipped institutions for the treatment of venereal diseases. A sufficient and competent staff should be employed and well remunerated in order to be able to afford time to properly care for these cases. The funds for such hospitals and dispensaries should be provided by the state. I listened with great interest to this paper, and believe that more papers on the subject should be written.

DR. H. W. STELWAGON, Philadelphia—I feel as several speakers have expressed themselves, that we will never make headway in the control of venereal diseases by legalizing prostitution or by recognizing it as a legitimate calling. I protest strongly against such an expression. We must cease to look on gonorrhea or syphilis as a joke, which is done over and over again by laymen and physicians. The young man must be plainly advised in his college days as to the dangers of such maladies, not only the serious consequences but the moral degradation resulting. I am sure if colleges would take this in hand at the beginning of each session and the students be talked to plainly, seriously and in good earnest, it would limit the contraction of such diseases very materially. They should be made to understand that such diseases are not only dangerous to themselves, but to others, and to their children. I have no sympathy with anything looking to the legalization of prostitution; I have no sympathy with the expression regarding it as a legitimate calling. We are not here to condone any crime; we ought to stand up against crime every time.

In regard to statistics: we all know that statistics are wrong. We have heard a great deal about the number of patients calling at dispensaries, hospitals, etc., but we all know that one patient frequently goes to four or five dispensaries. I have seen the same patient at three dispensaries. At my dispensary services we put one patient down as two patients if he has two diseases. If, for example, he has eczema and acne we put him down as two patients, in order that proper records of both diseases can be kept. The number of people applying to dispensaries is not so large as some would suppose.

DR. R. R. CAMPBELL, Chicago—I think Dr. Montgomery has sounded the keynote of prophylaxis of venereal diseases. In connection with education the first step is to educate the physician, and I do not hesitate to say that 85 per cent. of the profession who treat gonorrhea do not know when gonorrhea has been cured. They still follow the old idea that when the discharge ceases the disease is cured. They do not realize that having gotten the patient over his uncomfortable symptoms they are just reaching that point when it becomes hard for the attending physician to relieve him of the more serious condition resulting from an attack of gonorrhea. The gonococci can lie dormant for years and then be readily excited into activity. One case in the practice of Dr. R. W. Taylor that had laid dormant for 28 years, then became active. The same applies to syphilis. It is a matter of education. In the first place the education should begin with the medical student. The genito-urinary and dermatologic work of undergraduates in

colleges is considered of secondary importance, and as a consequence the student feels at perfect liberty to cut the clinics or cut the lectures that pertain to venereal diseases and dermatology, for he thoroughly appreciates that he does not have to pass an examination in these branches. If we could only make the members of faculties in our colleges realize this important point, to require an examination in those different branches as well as in others, we could then begin our education at the right point. To try to educate men who have gone into the country and are dependent for their further education on post-graduate work we will never make any progress toward venereal prophylaxis.

DR. WEISS—I wish I had the eloquence of a Demosthenes so that I might answer properly all these questions. I think I have sounded a note of warning about a dozen times, if not more, that if we expect to hasten the coming of the millenium and with it the moral evolution of the race, we will have to do something. I have emphasized the fact that social economic laws should be enacted in every state to diminish vice and the spread of venereal diseases. It is for the first time that individual prophylaxis is brought before an American medical audience, and I do so with a sense of reluctance. I need not defend my standpoint, as individual prophylaxis will in no way encourage profligacy or licentiousness, and I would like to call it out with a voice that could be heard all over; that we must drop this mysterious prudish standpoint of ours *because* we are on the side of morality; and at the same time we should quickly recognize the fact that things need a quicker remedy, a more tangible one than moral persuasion only. The physician should look on personal prophylaxis as a legitimate field of his interference without the least hesitation, as do continental authorities. I am sure to voice the sentiments of those assembled here when I emphasize the fact that physicians never neglect to admonish, to advise, to reprove, to blame, yea, even to chide their clients for indiscretions committed. They inculcate the necessity of chastity in the half-matured young man; they prevail on the eager candidate to postpone marriage until cured, and warn the erring young woman of her evil ways, urging her to amend. A profession that deals with the otherwise remunerative effects of sin so unselfishly and against its own material interest, surely can not be charged with promoting profligacy by holding sanitary measures paramount—to say the least—to moral regulation of vice. A profession that can not be outdistanced by any other regarding charity, devotion and purity of conception, need not, I am sure, be afraid to unfurl its flag of preventive measures to minimize what it could not avoid.

RESOLUTIONS ADOPTED.

After discussing Dr. Weiss' paper, the Section adopted the following preamble and resolution:

WHEREAS, There is a burning necessity to check the spread of venereal diseases, and assuming that the states can not with impunity ignore the condition, it lies in the province of the medical profession the task of recommending to the respective state legislatures and municipalities means, not reglementative, but social, economic, educative and sanitary in their character, to diminish the danger from venereal diseases;

Resolved, That the Section on Cutaneous Medicine and Surgery of the American Medical Association invites the Section on Hygiene and Sanitary Science to co-operate with the Section on Cutaneous Medicine and Surgery to bring about a propaganda in the different states looking toward the proper recognition of the dangers from venereal diseases, and to arrange for a national meeting under the auspices of the American Medical Association for the prophylaxis of venereal diseases similar to the International Conference for the Prophylaxis of Venereal Diseases which meets again this year under the authority of the Belgian government at Brussels.

HENRY W. STELWAGON, *Chairman*.

This was later submitted to the House of Delegates, which endorsed the action of the Section and adopted the following:

Resolved, That a joint committee of six from the Sections on Hygiene and Sanitary Science and Cutaneous Medicine and Surgery be appointed by the President to stimulate study in and uniform knowledge of the subject of the prophylaxis of venereal diseases, and to present to the American Medical Association a plan for a national meeting similar to the International Conference for the Prophylaxis of Venereal Diseases, which meets again this year in Brussels under the auspices of the Government of Belgium.

The Committee on Prophylaxis of Venereal Diseases consists of the following: Drs. Henry D. Holton, Brattleboro, Vt., chairman; George M. Kober, Washington, D. C.; W. H. Sanders, Mobile, Ala.; Ludwig Weiss, New York, secretary; L. D. Bulkley, New York, and Frank H. Montgomery, Chicago.

DETERMINATE FACTORS IN THE CAUSE OF INSANITY.*

EUGENE G. CARPENTER, M.D.†
COLUMBUS, OHIO.

It is questionable if there is any problem which has occupied the thought of medical men so diligently as that of the etiology of disease. It is one of the fundamental principles of our cult to determine the cause by the employment of every possible known means of diagnosis before applying our therapeutics or means of cure. A half century of time has been lost in the effort of medicine to make the etiology of general disease apply to or explain the clinical appearances as found in the insane condition. (I speak of insanity thus, for it is but an evidence of an abnormal brain state.) After a decade's experience the thought has constantly forced itself upon the writer that, in our endeavor to explain cause, too great stress has been placed on some so-called causes and too little on others. If the ordinary principles of etiology applied to the symptoms as found, then by ordinary knowledge of these principles we should be able to recognize the real status of the condition, and the usual remedial means employed should bring the usual results. But experience has taught us that this does not obtain, for to this time we have much to learn of etiology, and the employment of our best known treatment has resulted in the betterment of but 33 to 40 per cent. Out of this number 70 per cent. will recur, 20 per cent. will die before the opportunity for recurrence arrives, and 1 per cent. will possibly remain permanently well. These figures hold no comparison with the treatment of disease in general.

HEREDITY AS A CAUSAL BASIS.

In recent years it has been found by close detailed examination of the insane that many stigmata can be found pointing to predisposing cause as a primary factor, and as containing an explanation of the instability of those successfully reinstated in their normal state. In reviewing the statistical tables contained in the official reports of the hospitals for the insane, the proportion of cases credited to hereditary influences varies from 25 to 90 per cent., the average of all countries being about 60 per cent. Mercier says: "The tendency of late years has been to lay increasing emphasis on the hereditary factor in the production of insanity, but it is doubtful whether even yet the true bearing and significance of this factor has been recognized."

In a special examination of one thousand cases by the writer, made with particular reference to the stigmata of degeneration, it was found that at least 75 per cent. exhibited various signs of anatomic defects. Other investigators have placed them as high as 90 per cent. This finds a responsive remark by Berkley, who states in his "Mental Diseases," in speaking of the hereditary predisposition, that "This tendency, although it may sometimes be acquired, is much more frequently born with the individual, so that in the majority of the mentally afflicted we find directly inherited predisposition to insanity." Granting this basal factor to exist in this ratio in the etiology of all those who actually fall a victim to this disease, it does not argue that one so predisposed of necessity must ultimately become insane. Is it not our common knowledge that all persons predisposed to the development of tubercle bacilli within

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Richard Dewey and H. A. Tomlinson.

† The author of this paper died Oct. 19, 1902. See THE JOURNAL, xxxix, p. 1125.

their organism may escape through a lifetime, if not exposed to the conditions favorable to its propagation? Therefore, we are justified in holding that notwithstanding one be under the "tyranny of organization," there are after all determining etiologic factors, if exposed to which, certain psychopathologic conditions are sure to become established.

It is intended in this paper to call attention to what I take occasion to call *determinate causal factors.* Mercier declares "The causation of insanity may be summed up in two words, 'heredity' and 'strain.'" The former is responsible for instability of the nervous system, while in the latter the causes are multiform in character, comprising all sorts of stresses, physical and mental, direct and indirect, having to do with antecedent influences and environmental conditions; in brief, all those factors which attack the integral organic structure upon which normal mentation is dependent and tend to undermine the nervous constitution, lessen its resistance, cause a reduction in its potentiality, and thus bring about a mental collapse.

ALCOHOL AND DRUGS.

Among these stress causes are found the determinate factors already alluded to and to which I wish to call your special attention. At the head of the list must be placed alcohol and drugs. All authentic observers have yielded the palm to alcohol as ranking next to heredity in cause. Clouston credits it with 25 per cent. of all insanity; Peterson from 18 to 20 per cent. in males; Berkley, more conservative, with 10 to 30 per cent.; Kræpelin 10 to 30 per cent. in Germany; the British Lunacy Commission gives 22 per cent. in males and 9.1 per cent. in females. The writer's observation has shown it to have 12 per cent. of the annual admissions. This is a cause upon which we can place our finger. We know it to be toxic in its effects upon the human organization, and the pathologic changes it brings about in the various tissues of the body are well known. We see them in evidence upon the autopsy table, and what we can not see with the naked eye there we can see under the searching glance of the microscope. There is no chance for guess or cavil there. The misuse of alcohol is one of the preventable causes, and yet it contributes 12 to 20 per cent. of the inmates of our asylums. Not only that, but the law of heredity is ever providing communities with dependent clientele for the future through a progeny, the result of the participation of the alcohol misuser and inebriate in the marital relation. This legacy in the way of defectives propagated by the alcohol habitué is distributed generously as well among the feeble-minded, the correctional schools and the penal institutions. From this estimate of the extent it is figuring at present in the production of the degenerate classes, alcohol is one of the greatest factors menacing the perpetuity of the American race.

SYPHILIS.

While syphilis figures largely in the etiology of disease in general, amounting to two-thirds of those treated in some of our large city hospitals, it is difficult to estimate how important a rôle it plays as a causal factor in mental disease. It takes up its position in all regions of the brain, and its morbid process may take on different degrees of extension, and at the same time, with a few exceptions, there is no characteristic of its presence, this frequently depending upon its intensity and its position in the organ. Hughlings Jackson has shown syphilis of the nervous system to be a misnomer, and proved that the poison never attacks the nerve tissue proper at all, but only neuroglia, fibrous tissue, blood vessels, lymphatics, membranes or bony covering involving nerve tissue and its functions generally. In the Royal Edinburgh Asylum out of 3,145 cases there were found 16, or 1-6 per cent., of cases of syphilitic insanity. This small ratio might obtain in an aggregation from a Scottish district, but I believe 1 per cent. would not be placing it too high for the hospitals of the continent and of the United States. I take it that this small percentage has reference to those cases of insanity occurring in the secondary stages of the disease, and which in reality are rarely found in the wards of the hospitals for the insane. To paretic dementia, essentially a syphilitic brain disease, may be accredited about 5 per cent. of the insane population. The prevalence of antecedent syphilis in this disease has been stated differently by different observers. Magnan placed it at 4 per cent.; Siemerling at 11 per cent.; Kræpelin at 90 per cent.; Westphal at 40 per cent. in women; Binswanger at 50 per cent. to 69 per cent.; Erb at 52 per cent.; Mendell at 75 per cent.; Connolly Norman at 80 per cent.; Savage at 80 per cent. Dr. Stoddart in the July, 1901, number of the *Journal of Mental Science,* thinks 75 to 90 per cent. represents more closely the facts, and concludes, "that syphilis is so frequent an antecedent of paretic dementia that the non-syphilitic cases, if such exist, may for the present be regarded as a negligible quantity and that hardly anybody runs the risk of acquiring the disease who has not had syphilis." Crediting 4 per cent. to organic changes due to luetic arteritis, meningo-encephalitis, syphilomatous deposit and inflammations in membranes, bones, etc., a conservative estimate of insanity due to syphilis would be 8 to 10 per cent. Thus is recorded a second prevalent, preventable, determinate cause of insanity.

CEREBRAL TRAUMA.

Injuries to the head seem to hold a prominent place in the profession as an etiologic factor in insanity. Were this true as often as alleged, great weight would need to be given to it in the consideration of causes. In an inquiry as to the frequency with which injury causes entered into insanity two years ago, I found it greatly overestimated. Among those who had gathered data on the traumatic cause of insanity were Kiernan, who had found 45 cases among 2,200 patients; Hay 60 cases in 2,500; Starr regards 2 per cent. as a fair estimate; Clouston 1-3 of 1 per cent.; Krafft-Ebing found 1 per cent. in 462 cases. Out of 1,400 cases the writer found 10 cases, or .7 per cent. The consensus of opinion in regard to traumatic insanity, so-called, is that it may, and does, operate as a determinate cause in a small number of cases, ranging from .3 to 2 per cent.; that it follows an injury to the cranium where superimposed upon an alcoholic basis, or positive neuropathic predisposition.

TUBERCULOSIS.

Tuberculosis is found to be more prevalent among the insane than the sane. As long ago as 1863 Clouston, after making a close investigation of this subject, in a large number of cases, described a symptom complex as especially characteristic of what he calls phthisical insanity. This author ascribes a ratio of at least 2.7 per cent. of the admissions to Morningside to this cause on account of the uniform array of mental and bodily symptoms.

Comparing the symptoms of this class of patients with his picture of it as a special form, there does seem to exist a justification for his opinion. When con-

fronted with the fact that insanity is rarely found in hospitals for the tubercular, he argues that the mental symptoms appear long before the disease has advanced to any great degree, and the patients are committed to asylums instead of the special hospitals for the treatment of that disease. He insists that the physical conditions of brain anemia, viz., malnutrition, cachexia, blood poisoning, insufficiency of blood, which are always present antedating the appearance of the tuberculosis, are the cause of the early physical phenomena in some cases. The data gathered by myself tends to substantiate the position of this authority, for from the findings of 51 autopsies there were found five cases in which the cause of death was not tuberculosis, although active tubercular lesions were found. In seven cases there were no tubercular lesions in the lungs, but the bronchial lymph glands were either actively tubercular or contained evidence of old lesions. That 37 examinations of sputum revealed germs in 35 per cent. of the cases examined. That tuberculosis was the cause of death in 27.7 per cent. of the females, while 10.6 per cent. of the males died from this cause. Total deaths from tuberculosis being 12.26 per cent. From these proofs of its great prevalence among the insane, and that it is a positive entity in type, there is certainly reason in regarding it as a decisive etiologic factor.

PROGRESSIVE DEGENERATION.

There are individuals in whom the die of degeneracy has been cast in the first hours of the cellular arrangements of the ecto, meso and hypoplastic layers of their embryonic existence. From the very necessity of this fact beings are projected into life, anatomically, physically and psychically atypical and at certain crises of their lives indicate by their mental collapse that the wheels of evolution have been reversed and dissolution has been inaugurated. I refer to the insanity of pubescence, adolescence, paranoia and senility. The first three are forms of the so-called developmental insanities. In these persons a normal evolution of the body and brain apparently progress to a point where suddenly all the inherent potentialities seem to have become exhausted as evidenced by marked mental reduction. Not infrequently do these cases manifest unusual brilliancy in their earlier years of pubescence and adolescence, only to make the difference more striking when their hopeless dementia follows. Here, if sufficiently probed, antecedent history would throw a flood of light upon cause, and the frequently alleged vagary, masturbation or some other assigned cause equally incorrect, would not need to be so conveniently produced.

Senile insanity for the most part is expressive of terminal dissolution of the brain tissues. The atheromatous arteries, the atrophied convolutions, indicative of nutritional changes, call for little logic to explain diminished mentality of the aged, common physical signs of which are their restlessness, depression, dizziness and insomnia, accompanied by a corresponding loss of memory, inappreciation of time and place, while their thoughts and acts have reference only to things long past.

TOXEMIA.

Not a little literature has been offered of late years in reference to toxemia, dependent on external and internal causes. To such external causes as alcohol, morphin and cocain, already alluded to, may be added lead and mercury, each of which, in addition to the usual physical manifestations, also takes on an array of somewhat characteristic mental symptoms. Others to be mentioned are coal gas, carbonic acid and bisulphid of carbon. In Egypt hashish is a common cause of insanity. We can not note tobacco to be an active causal factor, although one case came under my observation in which there was a nicotin amaurosis that appeared to be positively caused by the excessive use of this narcotic. Emphasis has been given auto-intoxication as an etiologic factor, not only of disease in general, but also as a specific factor in morbid mental states, and has been rather warmly received by the profession. In support of this theory, conditions and symptoms have been referred by some investigators to the presence in excess of lithates, ptomains, xanthin, para-xanthin, uric acid and other chemical poisons. As a result of the absence of hydrochloric acid and other normal digestants in the stomach through faulty metabolism, fermentation and other abnormal processes takes place in which a series of chemical poisons develop. Wagner and Jaksch have attributed certain types of mental disease to certain nerve poisonous substances in the urine, viz., acetone, diacetic acid and oxybutyric acids.

The decomposition of albumin by the influence of bacteria in the intestines has been found by the physiochemist to result in the formation of such putrefactive products as indican, indoxyl, potassium sulphate, skatol or skatoxyl-potassium sulphate. These elements, it is claimed, are found in large quantities in the obstructive intestinal conditions.

Notwithstanding the vagueness and incomprehensiveness of the data at hand on the subject of auto-intoxication, and that the wise are asking "what is it" when it is mentioned, every practical medical man feels he sees enough clinically to justify him in the conviction of the truth of this theory, and the results of the investigations to date that it plays an important rôle in the cause of this disease. Apropos to this, the prominence given by some authors to rheumatic, choreic, diabetic, podagrous, puerperal and lactational insanities as special forms, is suggestive that all these might be indicated under auto-toxic types if our advancement in chemical pathology would allow it. In this branch of our medical knowledge is our future hope, and when that shall have been developed, no doubt toxemia and auto-intoxication shall have taken a prominent place in the list of determinate causes of insanity.

KIDNEY LESIONS.

From the fact that so large a percentage of our cases yielded positive pathologic nephritic conditions of various kinds, we are forced to the position that there is some connection between kidney disease and insanity. Both the cause of the disease and the mode of death are in keeping with this view. Again, chemical and histologic findings lend a strong color to this position. Of the 422 specimens examined the past year in our laboratory, 36 per cent. contained albumin, 11.6 per cent. contained casts, 20 per cent. contained hyalin and granular casts without albumin. Sugar was found in three cases. Fifty per cent. of the kidneys showed interstitial increase, 18 per cent. showed parenchymatous changes, 64.6 per cent. exhibited some kind of kidney impairment.

ACUTE INFECTIONS.

Infectious diseases, as typhoid fever, pneumonia, influenza and malaria, should be reckoned as decisive causal factors. In the acute psychoses changes in the vascular system and the effect of the toxins upon the nervous centers act as positive exciting causes. Not infrequently are these cases admitted to an asylum during a period of temporary delirium, after which the dis-

ease runs its usual course without any particular mental disturbance.

NERVOUS EXHAUSTION.

The investigations of Hodge, Mann and others have proved that positive changes take place in the nerve cells as a result of excessive exercise and fatigue as compared with rested cells. These proofs lead to the strong probability that like changes take place under the stress of such physical causes as mental overwork, overstudy, insomnia and others kindred to these, which induce nervous exhaustion. Again, the lowest point of exhaustion may be overreached, so to speak, and absolute cell degeneration follow, placing what was a remedial condition outside the pale of restitution. Moral causes appear to act in a majority of instances as direct causes of alienation, but the histologic evidences are that a pathologic basis is always established previous to its manifestation. While the moral features of a case of insanity frequently attract the attention, and are very alluring in the consideration of causes, they should not be permitted to overshadow all others as is frequently the case. In the light of the advancement of the psychiatry of to-day it is not sufficient to explain the circumstances of a mind diseased by assigning "grief," "domestic trouble," "religious excitement," "love affairs," etc., as the probable determining etiologic factor. Much of this sounds legendary, and should be allowed to pass by with the ancient myth of the moon.

DISCUSSION.

DR. J. H. MCBRIDE, Los Angeles, Cal.—The Doctor's statement that Hughlings-Jackson has said that the nerve cell is not directly attacked by the virus of syphilis is not quite correct, in that Dr. F. W. Mott was the first to make this generalization. Dr. Mott says that the syphilitic virus never attacks the nerve cell, but that it attacks the mesoblastic tissues only, namely, the blood vessels, lymphatics and neuroglia.

In regard to tubercular insanity: there is some merit, I suppose, in an etiologic classification, but I can not believe that the type of insanity described by Clouston in 1876 as tubercular insanity is really a distinct form. I should be glad to hear from Drs. Tomlinson and Dewey on this point. As a curiosity in this connection I have observed three cases of epilepsy during the past year in which the fits were associated with incipient pulmonary tuberculosis. Bright's disease is, of course, associated with insanity and bears doubtless an etiologic relation to it. Dr. Alice Bennett first called attention to it and Dr. Tomlinson has, I believe, written on the same subject.

DR. H. A. TOMLINSON, St. Peter, Minn.—Ten years ago, in a paper read before the American Neurological Association, I made the statement that I did not believe all of the influence of heredity was included in the direct transmission of any particular form of disease from parent to child; and I laid particular emphasis on this contention in connection with insanity. Since then I have continued my observations in this direction, and have taken special pains to verify the family history in every case coming under my care. It is my belief that no one ever becomes insane who is not primarily either unstable or defective; and that any constitutional condition present in the parents, which may have lessened their vitality, may bequeath to their offspring an unstable nervous system; while defect is particularly apt to be present in the children of the alcoholic, syphilitic and consumptive. It is probable also that the reason the nervous system is most affected is on account of the natural tendency of degeneration to begin first in those parts of the organism which are last in the order of development and most complex in their structure. I have observed further that the children of the insane are usually unstable, and that tuberculosis is more common among them than is insanity; while the primarily defective individuals have behind them a history of syphilis, alcoholism or tuberculosis; and singularly enough, not uncommonly cancer. The children of the insane suffer from the simpler psychoses and the recurrent forms of insanity, with entire absence of, or very slowly developing, mental reduction. Comparatively few of the children of the insane become insane, but a great many of them die of tuberculosis. It is equally common for the children of the tuberculous to become insane. In the hospital at St. Peter we have a great many cases of tuberculosis develop among our patients, but the subjects of the disease are not the children of the tuberculous, but of the insane and neurotic, thus showing a tendency to transmutation between two generations. I have never found anything in my experience to warrant the conclusion that tuberculosis is ever a direct cause of insanity. On the contrary, during the past ten years we have had only five people committed to the hospital who were suffering from tuberculosis at the time of the onset of the mental disturbance.

I was interested in what Dr. Carpenter said about injuries to the head. Every one who has had much experience among the insane knows that they have no significance in a causative sense with relation to insanity. Very few children grow up without having had some injury to the head, and severe traumatism is not uncommon; but how few of those injured ever become insane. These head injuries are given as the cause of the insanity because the relatives do not wish to admit, even to themselves, that they have an unstable or defective member of the family. I have occasionally, in my postmortem work, found evidence of cranial injury, but no degenerative change in the cortex beneath. There was, however, marked degenerative change in the cortical area covering the insula. This is the point where degenerative change begins, because it is the place where development ends, the area of the most complex functional activity in the cortex. Just why the blood vessels in this region should be the first to undergo degenerative change I do not know, but it is a fact in my experience that the middle and anterior cerebral arteries are the first to show evidence of atheroma—just as atrophy of the frontal lobes anterior to the precentral fissure is always in proportion to the degree of mental reduction present.

DR. RICHARD DEWEY, Wauwatosa, Wis.—The question that Dr. McBride asked as to whether there was a special form of psychosis developed as a result of tubercular disease is one of especial interest. It is my view from what experience I have had in this direction that there is not a characteristic tubercular insanity. It may be said that there is a melancholia that is very typical and very uniform among patients who have an active tubercular process going on in the lungs, and there are many cases which are strikingly similar in their development, in very many of which it would seem that the tuberculosis was a sequel to the insanity and the melancholia, and that the existence of the depression and stupor and inactivity of the body established a cessation of the ordinary exercise of the respiratory muscles, and that the change of the blood in the lungs and lack of aëration of the blood, led to the development of tubercular disease, which probably previously existed in the germ, but I do not myself believe that there is a special form of tubercular insanity. The general questions of causation, it seems to me, tend to resolve themselves more and more into larger and broader categories in which subordinate variations can be grouped, and there seems to be much truth in the remark which Dr. Carpenter quoted from Mercier, that heredity and stress were the two factors. Of course, we are still very much in the dark as to what is meant by heredity and there is still very much to be learned in this connection about the embryologic states, and the very much greater activity which is at present evident in the study of the brain changes, in the embryo, and in the ingrowing subject and in the adult, will lead to more definite knowledge than we at present possess as to what it is that is transmitted. We are much in the dark in this connection and do not know anything except that a certain tendency is transmitted, but what is the physical basis or structure on which it depends is something that remains to be sought out. Heredity means practically everything included within the individual's vital processes, physically and psychically, and strain refers to environment. Thus, if you take two individuals exactly alike, and subject one of them to prolonged and severe stress, and the other escapes it, one of them will

become insane and the other will not, though each may be of neurotic or insane diathesis, and probably none become insane who have not this defect. I think that the laws that are laid down in this matter are very instructive and will serve as a guide to much more accurate and broader views than we have heretofore been able to formulate.

DR. H. H. HOPPE, Cincinnati—A few years ago a friend who was studying nervous and mental diseases in Vienna returned and told me that Krafft-Ebing was so imbued with the idea that syphilis was the cause of paresis that he inoculated a series of 60 cases of paresis up to that time with the virus taken from fresh syphilitic chancres. Not one of these 60 cases of paresis developed syphilis. This tended to prove that they had all previously had the disease. I would like to ask Dr. Carpenter whether or not the results of this series of experiments have been made public.

DR. J. T. SEARCY, Tuscaloosa, Ala.—In the matter of heredity as an important factor in insanity, I would like to make the following suggestion: It is an established biologic principle that in those organs and structures in which hereditary variation is going on, most instability of structure is found. This is abundantly illustrated in domesticated plants and animals. While hereditary variability has improvement as its object, in the way of improved adjustability to a changed environment, still the very morphologic changes that are made are new structures, and consequently there is instability. Newness of structure means, in a certain sense, weakness; so that while variation is meant for improvement, it at the same time is a frequent cause of weakness. In degenerating individuals and families in the biologic world, we find frequent defects, abnormalities, and aberrances as well as more liability to disease in their newly varied acquisitions. Improvement of function comes by way of variation of structure; still, variation, in those families that do not continue the same efforts that beget the improvement, may be a source of ready deterioration. In our present-day civilization and for several hundred years, there has arisen much changed and excessive exercise of the cortical brain; very different from what was the case when we were rude savages roaming over the plains of Europe, when muscularity rather than brain-ability was our most prominent accomplishment. The requirements for brain-work have been for a long time increasingly a necessity that is very exacting. All of our early life is now taken up in study, and our adult life is strenuously occupied in brain-work. The result is, hereditary cortical variation in the way of improvement. But, following the general biologic rule, the newly varied brain structures fail readily, particularly in those individuals or families that do not keep up the same ancestral improving exercises. There are, therefore, nowadays, in brain structures and capabilities seen frequent signs of deterioration, of degeneracy, of defectiveness, and of disease. The increase of modern insanities, in this way, has hereditary cortical variation as one cause—if not its principal cause. The eyes, in conjunction with the cortical brain, are organs that are much worked in new ways in our modern civilization. We have largely changed from far-vision to near-vision in the uses to which we subject them with most strain and effort. Consequently we find them varying and their instability of structure occasions frequent abnormalities, asymmetries and tendencies to disease. The cortical-brain is varying, and so are its windows, the eyes; and we see increasing exhibitions of the defective instability of both in our most civilized communities. In this way, as Dr. Tomlinson quoted, "where evolution ends, insanity begins"; because when and where improving variation of structure stops, deteriorating and defective variation sets in.

DR. CARPENTER—In the first place, I do not know that Dr. McBride understood my paper exactly. What I meant to say was that syphilis did not attack the nerve cell or the neuron, but that it did attack the approximate tissue; the blood vessels, the connective tissue and the fibrous tissue; and that the damage to the nerve tissue was secondary. If it is proven that the nerve cell is attacked by the syphilitic virus, that is something more recent than has come to my knowledge.

In regard to tuberculosis and insanity, I think it should be kept in mind that tuberculosis is a destroyer of nutrition and in that way may do much damage to the system as a whole, in which the brain may participate especially, and in due time manifest itself in insanity by presenting a special picture. In the paper you may have noticed that a large number of the deaths were proven by the postmortems to be due to tuberculosis. I wish to remind you that these autopsies were not of cases recently admitted to the hospital. We should always keep in mind the fact that a large ratio contract the disease while in the institution. I think if there is anything characteristic of this form of the disease it is the depression of which Dr. Dewey spoke, and which I think is characteristic in all diseases due to infection, as is usually noted in typhoid fever, and in la grippe particularly. I would regard tuberculosis as a determinate factor in insanity much as I would regard bad hygiene and bad hygienic surroundings, poor food, and similar factors which tend to have a devitalizing effect on the constitution of the individual.

I understood my worthy colleague, Dr. Tomlinson, to make the statement that he believed all insane people to be possessed of a hereditary predisposition. It is my conviction, on the other hand, that there is a certain small percentage of cases of insanity due to infectious disease, and toxic conditions in which heredity play little or no rôle; that is, that infection may be the direct cause of insanity where there is no predisposition. We know that a small percentage of the cases of acute mania do recover and remain permanently cured. Berkley speaks of 4 per cent. that had remained permanently well after ten years. I believe that a small percentage of the cases of acute mania and acute melancholia do recover and remain perfectly well, and I believe these are the cases which are due solely to the infection without the element of predisposition entering into them. In regard to the most vulnerable point in the brain, I believe it is the district to which the cerebral artery distributes its branches. It is an accepted principle, as my colleague has intimated, that "dissolution begins where evolution leaves off," but it seems to me that it should be remembered that those parts of the body which are the most abundantly supplied by blood, and which contain the largest number of blood vessels, are the most frequently attacked by the neoplasms or degenerative processes, and it occurs to me that in these cases of insanity from infection the flood-tide of the blood is in the cerebral artery through whose branches infections and toxins are most probably carried. Hence the region most likely to be affected by the degenerative processes is the district supplied by the cerebral artery and its branches.

In regard to Krafft-Ebing and his syphilitic tests in paresis: from such information as I have been able to glean, I believe none of these cases that were tested showed any manifestation of the primary or the secondary symptoms of specific disease.

PRELIMINARY NOTE ON AN EXPERIMENTAL RESEARCH INTO THE MEANS OF CONTROLLING THE BLOOD PRESSURE.

GEORGE W. CRILE, M.D.
CLEVELAND, OHIO.

When the vasomotor center is exhausted stimulants such as strychnin are either valueless or harmful, because if the center is wholly exhausted it can have no effect, and if partially exhausted the stimulation will be followed by a deeper depression. Shock may be as readily induced by vasomotor stimulants as by injuries or operations; the former belong to the class of internal stimulants, the latter to that of external stimulants. Neither can be employed with advantage in the treatment of a shock produced by the other. Alcohol should be classed as a depressant. Nitroglycerin is of advantage only in certain diseases of the arteries. In digitalis the vasomotor factor in its effect is objectionable on the same grounds as that of strychnin. As to the cardiac factor in the action of digitalis, an increase in the heart's action, *per se*, has but a limited effect on the blood pressure in normal cases, but when the peripheral

resistance is lost, an increase in the heart's action has practically no effect on the blood pressure.

Normal saline solution is not in any considerable quantity retained in the blood vessels. When approximately 320 c.c. per kilo has been given, it causes death by asphyxia, due to the accumulation of the solution in the splanchnic area, mechanically fixing the diaphragm and the ribs.

Uniform mechanical pressure on the limbs and trunk by means of a pneumatic rubber suit gives a definite control of the blood pressure of from 25 to 40 mm. There are no unfavorable side effects. By this means patients may be placed in any posture during operations, because the pneumatic pressure creates an artificial peripheral resistance, causing the blood to flow back to the heart regardless of the posture of the patient. Adrenalin chlorid acts on the heart and the blood vessels, but not on the vasomotor center. In the normal animal, in every degree of depression, when the cervical spinal cord has been severed, or the medulla destroyed, or the animal decapitated, adrenalin gave a definite control within certain limits over the blood pressure—raising it even twice as high as the normal. It must be used carefully and in great dilution with saline solution. It was usually used in 1 to 50,000. In large doses it may over-stimulate the inhibitory mechanism in the heart. This may be prevented by atropin. A decapitated animal was kept alive for 10½ hours by adrenalin and artificial respiration. The effect of adrenalin on the heart and blood vessels may be obtained after death. Most animals could within certain limits be brought back to life again.

In one experiment 15 minutes after a dog's heart and respiration had entirely ceased adrenalin in 1 to 50,000 solution was introduced into the jugular vein, artificial respiration was given, and rhythmic pressure was made on the thorax over the heart. Normal respiration and blood pressure were re-established.

A remarkable effect on a patient was obtained by a combination of the pneumatic rubber pressure suit and adrenalin. The research extended over three years, and is based on observations on more than 200 animals and many clinic cases.

VACATION NOTES.

G. FRANK LYDSTON, M.D.
Professor of Genito-Urinary Surgery, Medical Department, University of Illinois; Surgeon to St. Mary's Hospital.
CHICAGO.

2. SAMOA.

As one approaches the equator he instinctively begins to shrivel a bit in anticipation of a pitilessly hot sun and sweltering nights—suggestive of a blazing moon. This unpleasant prospect is usually realized, but in entering the South Seas during the season of the "South West Trades" it is different, quite. The trade winds make the air delightful, night and day, unless one happens to have a state room on the lee side of the ship. Here, it is a bit stuffy, but not so much so as in a little cage of a room at home in summer. Weather which can be said to be really warm, is first encountered within three days of the equator—north, and on the third day after crossing the equator it is positively cool. The experience of increasing cold as one goes south, is odd when experienced for the first time.

I rather regretted that Neptune no longer boards vessels crossing the line. There was not even a ripple of excitement, and as for fun, it was entirely absent save for the evident apprehension of one young Englishman, who really more than half believed the statement of the waggish first mate, to the effect that vessels often bumped the line pretty hard in crossing.

It is not surprising that Robert Louis Stevenson should have selected Samoa as the ideal home spot of the world. The Samoan Islands are as beautiful as a dream of Paradise. Pago Pago, the principal seaport—after Apia—has a landlocked harbor surrounded by high, verdure covered hills, which is ideal. One is especially impressed with the virile greenness of the landscape, which suggests a blending of the tropical with the characters of that of our own eastern states. Imagine the scenery of portions of the Hudson, bordered above and below with palms and giant ferns, and the picture is complete. It is a pity that there are no hotel accommodations at Pago Pago, for the climatic conditions are peculiarly favorable for invalids.

The physique of the Samoan islanders attracts attention at once. The men are magnificently proportioned—rather better than the women. As I looked at these natives, I understood Mark Twain's comparison of white and brown skins. I chanced to see a half-naked fellow, as stalwart as possible and with a head like a Greek god, standing side by side with a good-looking young white man. The magnificent physique, clear brown skin, and noble features of the semi-savage made the white man look like a pretty poor specimen of the *genus homo*. Much depends on the point of view. The white man, as seen here, on the native heath of the Samoan Islander, has no occasion for self-conceit. I was promised still handsomer brown folk in New Zealand, and, as will be seen later, I was not disappointed. I saw but one incongruous thing among these primitive folk—a little native boy dressed in conventional civilized garb. He was an awful discord.

There is much of interest that might be said of picturesque Samoa, but I fear the blue pencil of the mighty editor; who is not in sympathy with non-medical articles in medical journals. At first sight it might be supposed that one would have some difficulty in gathering items medical in a crude little semi-savage community like Pago Pago. Indeed, the prospect of gathering something which might afford a *raison d'être* for a contribution to THE JOURNAL seemed to me at first rather gloomy. After poking about the place for a few hours, however, I changed my mind. The first thing I noticed was the "up-to-dateness" of the Samoans. Uncle Sam had ordered all of the natives to be vaccinated, and the entire population was nursing sore arms. I was informed that secondary axillary glandular infection was frequent. I saw several cases of this kind. Pus infection is frequent there in all sorts of surgical conditions, especially among the natives. Another "hall-mark" of civilization was a native with a saddle nose and deformed superior maxilla from syphilitic necrosis. As one intelligent native expressed it, "the white sailors bring plenty of both diseases." Among a crowd of natives whom I saw at Pago Pago, was a typical albino. He was a pure-blooded Samoan, and his pink skin, light eyes, blonde hair, bushy white eyebrows and scanty white mustache looked weird enough beside the dark skins and black (or chemical red) hair of his fellows. Apropos of blonde hair, I was amused to note that even Samoa has its "bleached blondes." Blonde and red hair among the natives—both men and women—is frequently seen. They bleach it to varying shades with quicklime. The feminine combination of a single, none too ample garment, a very ample figure, brown skin and bushy reddish blonde hair would give a State Street dude heart failure.

The prevalent diseases of Samoa are pneumonia, simple continued fever, and elephantiasis. Fully 15 to 20 per cent. of the natives have elephantiasis in one form or another. Pneumonia is frequently met, and despite the ignorance and superstitious malpractice of the natives, most cases recover. It is very fatal, as with us, among the aged. Meningitis or nephritis usually occurs as a complication in fatal cases. The natives think that the disease is due to a devil within the chest, who keeps the patient from breathing. The devil is exorcised by exercising the patient—forcing him to walk about, or at least sit up.

Pago Pago has a government hospital, a little one-story

affair that looks unpromising enough. But it is a good service, all the same, and although it has a capacity of only about fifteen in-patients, good work is being done there. The clever young naval surgeon in charge displayed a trophy in the form of an appendix, and showed a recovered patient. The case was that of a sailor, taken suddenly with characteristic abdominal pain. He was operated on 36 hours later. The appendix was gangrenous and had sloughed off. It contained several fecal stones as large as a date seed, and lay free in the abdominal cavity. There was no walling off. A portion of omentum was gangrenous and adhered to the appendix. No drainage was used primarily, but the wound had to be reopened and drained because of necrosis of a small area of bowel. Gas escaped, but no feces. Recovery was perfect. The surgeon thought he should drain next time—and I quite agreed. Appendicitis in the South Sea Islands! Verily, the world do move.

Among other cases I saw the successful result of a recent Pirogoff amputation, and a complicated hare lip and cleft palate operation in which resection of the jaw and formation of an osteal flap from the intermaxillary bone were resorted to. I saw a number of cases of elephantiasis. Among the recent operations was a case of tracheotomy for edema glottidis, apparently following some simple throat infection. Through the ignorance and maltreatment of the patient's native friends, this case was lost—an entirely unnecessary result.

There are many eye cases—corneal ulcers largely. Iridectomy is a frequent operation to remedy defective vision resulting from these. Much to my surprise I saw one case of bronchopneumonia in a child. Apropos of pneumonia, the explanation of the favorable results which occur, despite native superstition and ignorance, is probably the practically out-of-door treatment it receives. This point is not without its lesson for physicians of more civilized communities.

Laying aside professional enthusiasm for the moment, what most impressed me at Samoa was the fact that it belongs to our Uncle Samuel. The Navigator Islands are a long way off, but they are pretty, and they fly Old Glory.

(To be continued.)

Clinical Report.

A CASE OF DIPLACUSIS MONAURALIS.*

EMIL AMBERG, M.D.
DETROIT.

Mr. G. T. N., aged 28, consulted me in the beginning of May, 1902, and complained especially that he was hard of hearing in his right ear and that some tones sounded double.

The hearing test showed: 1/100-150 i; watch 6.5/100-150 i; + Rinné +; Weber = After use of catheter; 3/100-150 i; watch 16/100-150 i.

Between the time mentioned and Aug. 16, 1902, the patient was treated at irregular intervals. His main complaint was ringing in the right ear, impaired hearing in same and the very annoying and irritating phenomenon that he heard certain tones double. When the left ear was tightly closed and a tuning fork was sounded, patient heard two distinct tones in his right ear; one seemed to be just the octave of the other.

Under treatment with the Eustachian catheter and sodium bromid, and incidental nasal treatment, the symptoms disappeared. Later I understood that the patient noticed the phenomenon first one morning when his little child was yelling, at which occasion he heard sounds of a certain pitch double. Under date of Nov. 17, 1902, the patient writes me, in part:

> I am pleased to add that since my last visit to your office everything seems entirely normal. No double tones, no ringing, and my hearing is as good as it ever was in the past. I am naturally very much pleased, etc.

This case is apparently one which must be classified as diplacusis harmonica monauralis.

According to Politzer,[1] diplacusis is a rare disease. We discriminate between, 1, diplacusis binauralis (*a*) dysharmonica, (*b*) echotica; and 2, diplacusis monauralis. According to Barth[1] diplacusis binauralis is an affection of the middle ear, and he thinks that the affected ear does not hear another tone than the sound ear, but that it hears it only with a different pitch. Jacobson[2] refers the affection to the labyrinth. Kayser[3] says:

> The explanation of diplacusis dysharmonica is somewhat difficult. The most simple way is to base our explanation on Helmholtz's theory of the function of the membrana basilaris of the cochlea and to regard it as a condition of this membrane, which is out of tune perhaps by a change of tension (Wittich, Knapp).

The diplacusis binauralis echotica consists in the phenomenon that a sound is heard later and weaker in the affected ear. The diplacusis monauralis, illustrated by the case reported, and apparently a very rare affection, is confined to one ear, as the name implies. Alt of Vienna, in an exhaustive essay[4] entitled "Disturbances of Musical Hearing," says, on page 222:

> I regard diplacusis monauralis in which tones are heard double or multiple in the affected ear as a disturbance of musical hearing in neurasthenics in the sense of nervous symptoms, because it has always been observed in nervous people when there was an ear affection present, and because it disappeared spontaneously within a few days or weeks.

I may add that diplacusis in rare cases may, perhaps, be of interest from a forensic point of view in declarations of witnesses, and furthermore, that we may well remember the symptoms in mental disturbances.

New Instrument.

A NEW INSTRUMENT TO PROTECT THE BRAIN WHILE DOING CRANIOTOMY.

F. C. SCHAEFER, M.D.
Professor of Surgery in the Post-Graduate School and Hospital; Gynecologist to St. Elizabeth's Hospital; Surgeon-in-Chief to St. Hedwig's Hospital, Etc.
CHICAGO.

Every surgeon who has used the Gigli saw in opening the skull is cognizant of the fact that there is great danger of

Fig. 1.—2, Watch spring; 3, brain protector; 4, Gigli saw.

sawing through the dura mater, arachnoid and pia mater into the brain tissue. The longer the cut the greater the danger, on account of the convexity of the brain surface. The saw forms the string of a bow, the latter being represented by the arched skull bone. It is practically impossible to make an incision much over three centimeters long without damaging the brain or its coverings. Having known this accident to occur in the hands of experienced operators, I concluded to make an effort to overcome this difficulty and devised a brain protector, or shield, which is herewith illustrated.

Fig. 1 shows the parts of the mechanism.

Fig. 2 represents my method for controlling hemorrhage from the scalp.[5] A rubber tube or cord is wound twice around the head and pulled taut; stitches b. b. of silk thread are carried through the scalp and tied around the constrictor at three or four points, to prevent the latter from slipping. I have used this method for ten years with satisfaction. Fig. 2 shows the first step in using the brain protector. The watch spring (2)

and brain protector (3) connected are passed between the skull and dura mater from the first through the second trephine opening.

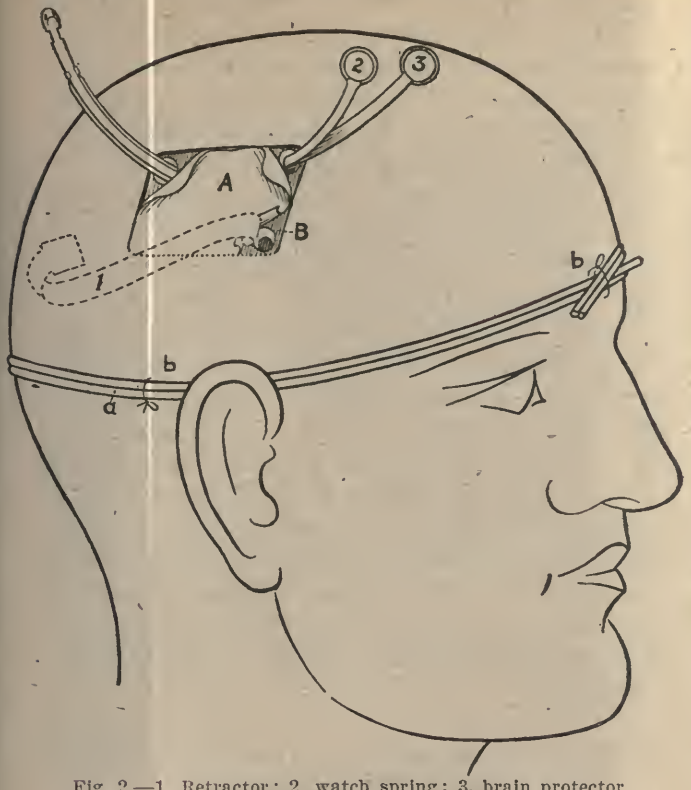

Fig. 2.—1, Retractor; 2, watch spring; 3, brain protector.

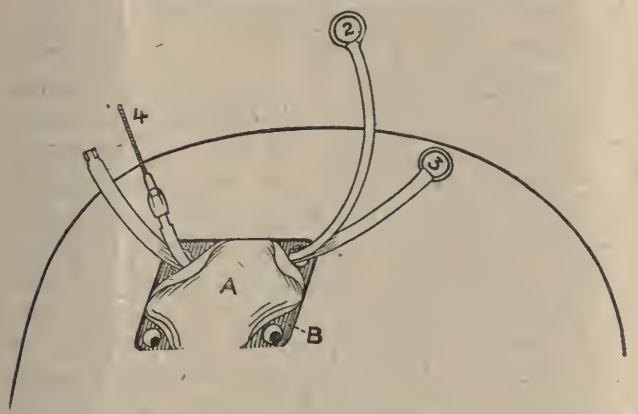

Fig. 3.—2, Watch spring; 3, brain protector; 4, Gigli saw; *A*, scalp; *B*, skull bone.

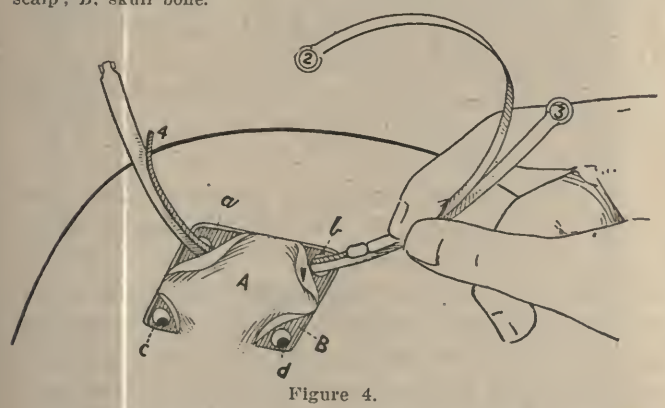

Figure 4.

Fig. 3 shows the second step. The brain protector (3) and watch spring (2) are separated, and the Gigli saw (4) is attached to the nub of the spring.

Fig. 4 shows the technic for pulling the watch spring (2) with Gigli saw (4) attached through the openings of the skull, leaving the brain protector (3) in position. The saw having emerged from the cavity is detached from the watch spring (2) and is now in position between the skull and brain protector, ready to cut through the bone. See Fig. 5, B, bone; 3, brain protector; 4, Gigli saw; C, dura mater. In sawing bring the saw obliquely through the bone so as to make a

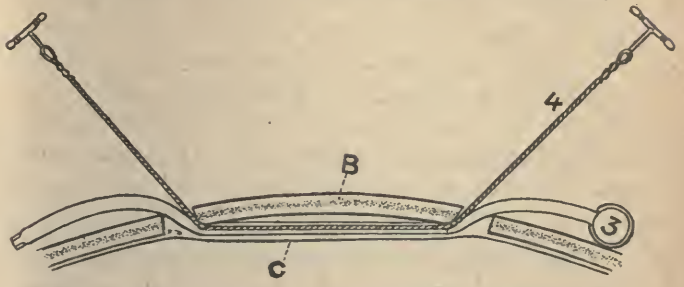

Fig. 5.—*B*, Bone; *C*, dura; 3, brain protector; 4, Gigli saw.

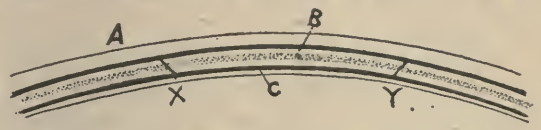

Fig. 6.—*X*, *Y*, Oblique cut; *B*, bone lid; *A*, scalp.

ledge (Fig. 6, X Y) for the bone lid to rest on. After having cut through one side of the intended lid, the same procedure is carried out as in Fig. 4 from a to c, and b to d. From c

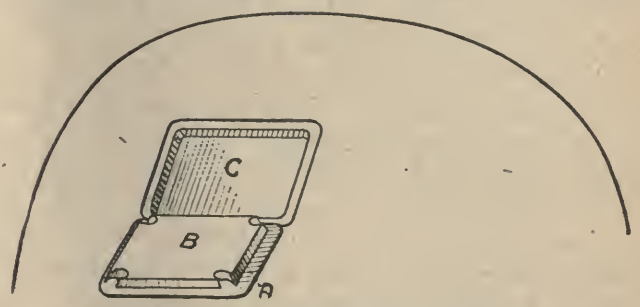

Fig. 7.—*A*, Scalp; *B*, bone; *C*, dura.

to d the saw is carried through the inner table only, indicated by dotted lines in Fig. 2.

Fig. 7 shows the lid of the skull turned down: B, bone; C, dura; A, scalp.

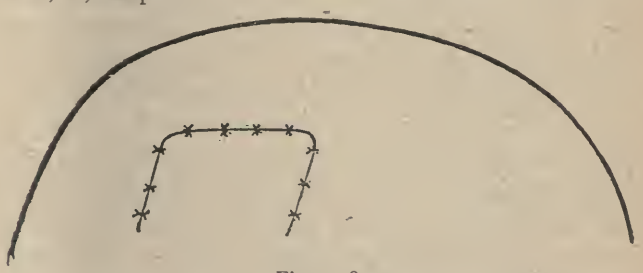

Figure 8.

Fig. 8 shows the lid replaced, and Fig. 6 a vertical section showing lid resting on ledge X Y.

The advantages of this instrument are apparent at a glance. There is absolutely no danger of sawing into the dura mater, an accident which frequently occurs when the Gigli saw is used without the protector. By sawing obliquely a beautifully even trap-door is formed, leaving a substantial ledge for it to rest on when closed. Any trephine with ¼ inch lumen may be used with the instrument.

To Destroy Odor from Ulcers.—If iodoform gauze be saturated with a solution of the compound tincture of benzoin and applied in cases of foul-smelling cancers and open malignant ulcers, the odor which renders life a burden, both to the patient and attendants, will be completely destroyed.—*Toledo Med. and Surg. Reporter.*

SATURDAY, JANUARY 24, 1903.

THE INCREASING PNEUMONIA MORTALITY.

Nearly three years ago[1] we called attention to the fact that statistics showed that pneumonia was causing more deaths than tuberculosis. We believe that we were the first to call attention to this fact, but it is becoming generally recognized.

The circular issued by the health department of Chicago for the week ending January 17 begins with the statement: "Since the census year 1900 pneumonia has claimed more than one-eighth of all the victims of the Grisly Reaper in Chicago; one-third more than consumption and 46 per cent. more than all other contagious and infectious diseases combined, including diphtheria, erysipelas, influenza, measles, puerperal fever, scarlet fever, smallpox, typhoid fever and whooping cough, the total of which deaths was 4,489 as compared with a total of 6,562 deaths from pneumonia." This statement is a striking one and certainly confirms our earlier assertions as to the predominance of pneumonia over other infectious diseases as a cause of mortality. While consumption has steadily decreased in its mortality, pneumonia is taking its place, and what was then first shown by us to be true of the vital statistics of Chicago and a few of the northern states, has, as shown by the figures here presented by the Chicago Health Department, been proven true of the country as a whole. While pulmonary tuberculosis has decreased from 18.21 per 10,000 population in 1880 to 14.44 in 1900, pneumonia has increased from 12.56 in 1880 to 13.49 in 1900, thus making a decrease of 20.7 of the deaths from consumption and an increase of 7.4 per cent. from pneumonia during the twenty years. Going still farther back, the deaths from consumption in 1860 were 25.28 per 10,000; in 1900 they were 15.30 per 10,000, a decrease of nearly 40 per cent. in forty years. From pneumonia the 48 deaths in 1860 in Chicago represent a rate of 4.40 per 10,000. In 1900, the 3,389 deaths within the city of Chicago represent a rate of 19.95 per 10,000, an increase of over 350 per cent. of pneumonia mortality.

It is customary to regard the increase in pneumonia mortality in the last decade or so as mainly due to the influenza infection which has been prevailing throughout the land. To a certain extent this is true, but the figures published by us in 1900, as well as these later ones, show it is not altogether the case, and we do not think that it can be so considered at the present time. Why some diseases increase in prevalence and mortality and others decrease is still one of the problems medicine has to meet, and we do not know of any more important one at the present time than those involved in the questions of the relative fatality of tuberculosis and pneumonia. The so-called "great white plague" may soon be considered a very secondary scourge to the human race if the increase of pneumonia mortality continues.

In conclusion we can not do better than quote from our former editorial: "While we are giving our attention to tuberculosis, a disease that is apparently on the wane, if only to a slight extent, we might divert our minds with one that is apparently increasing among us. It is not necessary to excite alarm, but a little more attention to a disorder that has, we have reason to believe, a widely varying range of virulence and which, in our northern climate, is our most fatal disease for at least half the year, would not be out of place. The fact that it is so closely related in its morbidity to climatic conditions would seem to indicate the chief line of prophylactic endeavor, but there are other factors also to be considered. At the present time it appears to be getting a little the better of us, and it is for us to find the reason why."

1. See Editorial, Journal A. M. A., April 14, 1900, p. 942.

CONSERVATIVE METHODS IN THE TREATMENT OF PROSTATIC HYPERTROPHY.

Within the past few years operative methods of treating nearly all cases of prostatic hypertrophy have found many enthusiastic supporters. The Bottini operation and the different forms of prostatectomy have largely come into fashion, replacing castration and vasectomy, which were in vogue a few years ago. The fact that the question of operative treatment is still unsettled is attested by criticisms by good men of all the operations which are at present in general use. The adherents of prostatectomy condemn the Bottini operation with some justice because of the uncertainty and possibility of cutting through the bladder when operating in the dark. The adherents of the Bottini operation point out the dangers of so extensive an operation as prostatectomy in old men much weakened by disease. Bier's operation of ligation of the iliac arteries has practically gone into entire disuse, and we hear but little of the old-fashioned method of treatment of extreme cases of suprapubic or perineal cystostomy.

Thorkild Rovsing,[1] professor of surgery at the University of Copenhagen, has recently published an article giving the results of his own experience in various methods of operation and speaking strongly in favor of more conservative methods than are now in general use. He finds that various operators have placed the mortality of the Bottini operation from 5 to 33 per cent., and even Freudenberg, one of the strongest advocates of the operation, admits a mortality of 8.5 per cent. in 318 cases which he has collected from the literature.

1. Archiv für Klinische Chirurgie, 1902, lxviii, 934.

Prostatectomy gives an even larger mortality, and the less severe operations of castration and vasectomy show a comparatively small per cent. of cases permanently benefited. Rovsing, in concluding his article, advocates that patients who are not in specially bad condition, who have only a moderate amount of residual urine and who have intelligence and facilities for catheterization, be treated by systematic catheterization in preference to any of the operative methods. Those cases in which there is total retention or in case of severe cystitis and other complications he believes are preferably treated by suprapubic cystostomy. He performs the operation under local anesthesia with cocain solution, inserting a drainage catheter which can be left for an indefinite time, and by the apparatus which he employs soiling of the patient's clothing is avoided. Out of a considerable number of cases in which he has employed this method of treatment none of the patients have died as result of the operation, and in many cases in which the patients were in an apparently desperate condition so complete a recovery resulted that they were able to get about and resume their employment.

It would seem from this and from other recent articles on the subject that there is a tendency to protest against the ultra-radical operative methods that have been so strongly advocated.

PROPHYLAXIS OF BALDNESS.

If anyone had insisted 25 years ago that tuberculosis was only slightly hereditary, but distinctly communicable, they would have been laughed at. The germ theory has now become a doctrine of ever-widening scope, and we realize that many affections are directly communicable and only a few hereditary. At the present moment it seems that even for so old-fashioned an affection as baldness a complete change of opinion as regards etiology is taking place. As with tuberculosis, so it has long been noted that baldness is likely to run in families. The sons of bald fathers are all the more likely to become bald young, and it is not the rule to find a single bald brother where there are a number in a family. On the other hand, daughters seldom become bald, but then the women folk rarely use the combs and brushes of the male members of the family, while boys not only use such articles in common, but often exchange hats, have their hair cut frequently at barbers, and in general are not rarely in circumstances in which they are likely to contract the disease, if it is communicable.

It is nearly ten years now since Sabouraud at the Pasteur Institute pointed out that premature baldness is practically always associated with the presence of certain bacteria. The seborrheic condition causing what is known as dandruff, on which early baldness probably often depends, he demonstrated to be a very probable result of the presence of these micro-organisms. Bacteriologic investigations made since have tended to confirm this opinion, and while they have failed to show the existence of any specific germs, they have made it appear probable that microbes play an important rôle in causing the increased desquamation of the epithelium which chokes up hair bulbs and finally leads to their obliteration. Undoubtedly the ordinary conditions of scalp hygiene among men are favorable to the development of these germs. The circulation to the scalp all comes from the vessels of the neck and finds its way over the bony skull to be distributed to the hair bulbs. It is especially likely to be interfered with by the pressure of the hat band, and that this is an important factor in the etiology of alopecia can be seen from the fact that baldness always begins just above the occipital prominence at the back or above the frontal bosses anteriorly, that is, just where the pressure of the hat band on blood vessels is most likely to be occlusive. This interference with the circulation lowers the resistive vitality of these parts of the scalp and consequently provides opportunities for the growth of micro-organisms. It must not be forgotten, moreover, that these three points mentioned are especially liable to infection. The comb and brush are used particularly in arranging the whorl of hair in the occipital region and in parting the hair and brushing it back over the frontal bosses anteriorly. If infection plays an important rôle, then, in the production of baldness, these are just the parts that, theoretically, should be first affected, and from which infection should spread to the other parts of the head. As a matter of fact this is what occurs in practice.

Greater care should be taken with regard to brushes and combs, especially in families in which early baldness is the rule. The hair brush should be dipped in an antiseptic solution several times a week. Combs should be boiled regularly and frequently, and under no circumstances should members of precociously bald families use other combs or brushes than their own, or allow them to be used on them, in barber shops, unless they are assured of their sterilization beforehand. These precautions may seem a high price to pay for the prophylaxis of premature baldness, and many will prefer to take the chance of becoming bald, but some have such a horror of the affliction that they will willingly put themselves to much trouble to prevent it.

A RUSSIAN LIBEL ON PHYSICIANS.

A Russian writer of fiction, one Veresayeff, or Smidovitz, has recently made something of a sensation by a libelous work on the medical profession. He claims to have studied medicine, but relinquished practice because he had not the nerve to use the knife and open an abscess, and consequently lost his patient by septicemia. Accepting this as a fact one can allow something for such an individual's idiosyncrasies, yet they do not justify his publication of his libelous fancies as facts, and making such statements as that human vivisection is a common practice; that every medical discovery is

made at the expense of the lives of scores of hospital patients ruthlessly sacrificed in experiments, and that murder in the name of science is constantly being performed. This work will probably be soon put in a form accessible to American readers, but we need not go abroad for all of this class of literature. We have plenty of ingenious fiction writers with an abundant lack of conscience to stimulate their mischief-loving propensities. A recent communication in one of our great dailies is an instance of the point, and we have before us a clipping from a local Iowa paper which makes the statement with apparent full belief in its truth, that it is a regular practice of the medical colleges in Chicago to purchase from gypsies healthy children for the purpose of clinical experiments and demonstrations.

However ridiculous or improbable, these stories find some believers, and these not always among the most ignorant. The antivivisectionists take them up at once and make the most of them for their purposes, and there are yet others who accept them without criticism from the mere habit of credulity. Some of the mud, of course, sticks, and it helps the quacks, the faith curers and all the tribe that fatten on human delusions. They, of course, encourage it, and it is easy to perceive the taint of their influence in the anti-vaccination and other tendencies of the antivivisectionists and all the other slanderers of the profession. As the only object of experimentation is to obtain what may be of benefit to mankind, we may claim, in some measure, the reward of those who have all manner of evil said against them falsely for righteousness sake. The scientific devotee to whom human life is nothing, and who is devoid of all human sympathies, is, we believe, unknown among physicians; we have never met him outside of fiction.

Whatever is said or done, one thing is certain, the public does not lose faith in the honest physician. It may go astray on quackery and a part of it may be joined to its idols for a time, but our profession will be in demand till that happy time—which only the rainbow chasers foresee—comes, when preventive medicine has done its perfect work and disease is abolished. That is an ideal which we may approach but can never attain.

PRIZE ESSAYS ON TUBERCULOSIS SANATORIA.

The first number of the London *Lancet* for this year fills its original department with the three prize essays in the competition for the plans of the king's sanatorium. The first, by Dr. Arthur Latham, is a practical monograph on tuberculosis sanatoria. Beside the very complete architectural details on the modified pavilion plan, it gives elaborate statistics and an historical introduction, and a discussion of the questions of immunity and infection as regards tuberculosis, and full comparative statements of institutions in various parts of the world, not only as to their physical features, but their methods of treatment, sanitary arrangements, etc. The other essays, by Drs. F. J. Wethered and Egbert C. Morland, are also meritorious and elaborate, but, in our opinion, less so than the first, though all three supplement each other and cover the subject very thoroughly. As a whole the number is a valuable contribution to the sanatorium treatment of tuberculosis and will be, in a measure, a standard document for some time.

THE TRANSPORTATION OF ANIMALS.

A bill is proposed in Congress to allow animals, while being transported in cars, to be kept for forty hours without being unloaded. The statute which this bill is proposed to amend places a limit of twenty-eight hours. It is easily realized that meat suffers a great deterioration when animals suffer as they will under such cruel regulations. It is often made unfit for food. There are other good reasons for a protest which do not concern us as medical men—for example, the cruelty to the animals. Further, if this measure purports to be for the purpose of saving in the cost of meat to the consumer, it is not likely to accomplish this while the combine is free to put the saving into its own coffers. The proper way to transport meat is in refrigerator cars. The proper place to kill cattle is as near as is possible to their free and healthy life on the field and with as little exhaustion, fright and suffering as can be. The less of these forty-hour runs such as this bill would legalize the better for those who eat the meat, as well as for the animals.

SECTARIANISM IN MEDICINE.

A deep, dark and dangerous conspiracy has been unearthed by a member of the homeopathic medical department of Michigan University.[1] It is, in short, an attempt under the auspices of the American Medical Association to amalgamate and ultimately annihilate the homeopathic school of practice. This is being done by the publication of the fact that any reputable and legally qualified physician who will agree not to profess or practice medical sectarianism is eligible through the county societies to membership in the Michigan State Medical Society. This does not seem at first sight nor after due consideration to be a very criminal proposition. Nor is there anything in the past professions of the homeopathic school to permit it consistently to object. It has flourished on its *soi disant* reputation of being a "new school," and inferredly a broader, better and more liberal body of practitioners than the "old school," whose alleged persecutions have been its best capital. The sudden wiping out of this stock in trade is naturally a blow to the invested interests of homeopathy—hence these tears. They mean that homeopathy has been existing on a name, that its progressive practitioners recognize the fact and that the higher principled among them, in fact, all who are worthy, are ready to honestly admit it. We believe that there are many such and that they are the very cream of the homeopathic profession. The same is true of the eclectics, one of whose journals also prints a similar tirade from one of its contributors. The offering of an olive branch, however, to the medical editors, medical professors and other official members of the irregular schools is a most uncomfortable and unwelcome local

1. The Medical Century, January.

application of coals of fire to their heads. We could ask no better indication that the liberal policy is likely to be effective than just such utterances from those whose financial interests are involved in the continued existence of the sectarian schools and journals.

METHOD OF INFECTION IN TYPHOID IN INFANTS.

We publish in this issue an article[1] with its discussion on typhoid fever in infants, in which the method of infection seems to cause more difficulty than we consider justified. Thompson is quoted as saying concerning typhoid fever that "from its etiology its occurrence is impossible in breast-fed infants." Brush says, "What I can't understand . . . is, if typhoid is a water-borne disease, how the nursing babe can get it." Cotton remarks, "I do not think we should let this subject go out with the impression that children are exempt from typhoid because they do not drink water. . . . That typhoid may be nursed from the mother's breast there seems to be little doubt." These remarks suggest a valuable field for clinical observation, namely, whether or not typhoid may be transmitted through the mother's milk, but in this discussion there seems to be left out of consideration the fact—it seems to us to be a fact—that almost every child imbibes water in different ways. If we are to believe there is a basis for the warnings given by those authorities who emphasize the danger of washing utensils in typhoid-laden water, these babies have many possibilities of being infected. But allowing that to be an almost impossible source, may we not consider that the majority of these babies are frequently given medicine in unboiled water? The most common way, however, would seem to be the use of water as a drink, since mothers are continually advised to give their babies water between nursings. In what way may we be sure that a given child never has had water to drink?

Medical News.

DISTRICT OF COLUMBIA.

No Action on the Army Canteen.—The committee on military affairs of the House of Representatives has decided to take no action during the present session of congress on the canteen question.

Physicians to the Poor Enjoined.—The board of charities has sent the following report and recommendations to the commissioners of the District urging their adoption:

A report having been received by the board of charities that physicians to the poor have occasionally made charge for issuing to poor patients certificates for illness to enable them to draw benefits from insurance companies, on investigation, was found to be true. The board is of the opinion that a physician to the poor should not be allowed to collect fee of any kind from patients treated by him as physician of the poor and carried on his list as such and to whom medicines are supplied at the cost of the district. They recommend to the commissioners the adoption of the following: "Physicians to the poor while acting in capacity of such are forbidden to receive fees for any service rendered their patients whether such service is in the nature of issuing certificates or otherwise."

Reed Memorial Meeting.—A memorial meeting of the Medical Society of the District of Columbia in honor of the late Major Walter Reed, U. S. Army, was held Dec. 31, 1902. The president, Dr. Samuel Adams, read an address in which he referred to Dr. Reed's career in the District of Columbia as a member of the society. Medical Director Robert A. Marmion, U. S. Navy, presented a biographical sketch; Lieutenant-Colonel Jefferson R. Kean, U. S. Army, considered him as a medical man in the Army; Dr. Albert F. A. King mentioned his qualities as a teacher; Dr. Chas. W. Stiles commended him as a medical writer. General Leonard Wood, U. S. A., spoke in laudatory terms of Dr. Reed's medical work in Cuba, and Dr. William H. Welch, Baltimore, referred to him as a scientific investigator.

Consulting Staff, Government Insane Hospital.—Dr. Alonzo B. Richardson, superintendent of the Government Hospital for the Insane, appointed the following physicians to the consulting staff: Internal medicine—Drs. Samuel S. Adams, G. Wythe Cook, Sterling Ruffin and James D. Morgan; general surgery—Drs. J. Ford Thompson, George T. Vaughan, William C. Borden and William P. Carr; gynecology—Drs. Joseph Tabor Johnson, Henry L. E. Johnson, J. Wesley Bovée, and Isaac S. Stone; ophthalmology—Drs. Swan M. Burnett, D. Kerfoot Shute, William K. Butler and E. Oliver Belt; laryngology—Drs. Charles W. Richardson, J. Julius Richardson, Walter A. Wells, and Frank T. Chamberlain; genito-urinary—Drs. D. Percy Mickling, Albert F. King and Wallace Neff; medical zoology—C. W. Stiles and Thomas A. Claytor; bacteriology—Drs. William B. French and Henry D. Geddings.

Washington Post-Graduate Medical School Opened.—The opening exercises of this school were held in the public hall of Columbian University January 12. Addresses were made by Professor Needham, president of Columbian University; Gen. George M. Sternberg, president of the school, and Dr. William H. Welch of Johns Hopkins Hospital, Baltimore. The officers and directors of the school are Gen. George M. Sternberg, president; Dr. J. Ford Thompson, vice-president; Dr. George M. Kober, secretary and treasurer, and Surgeon-General Walter Wyman, Surgeon-General Robert M. O'Reilly, Drs. Alonzo B. Richardson, Dr. Samuel S. Adams, Swan M. Burnett, Joseph T. Johnson, Sterling Ruffin, Edward A. Balloch, E. A. de Schweinitz, Henry L. E. Johnson, and William C. Woodward, directors. The clinics will be held at the several hospitals every week-day from 9 a. m. to 2 p. m. Laboratory work will be conducted daily from 2 to 5 o'clock. The teaching force numbers 104.

ILLINOIS.

Personal.—Dr. and Mrs. LeRoy O. Jenkins, Paris, left for a European trip, January 20.

City Hospital Contract Let.—The contract for the erection of the Rockford City Hospital has been let. It is expected that the building will cost about $50,000.

Officers of Cook County Hospital Staff.—At the meeting of the staff, January 15, Dr. Frank Billings was unanimously chosen president, and Dr. L. Blake Baldwin was re-elected secretary.

Harlem Schools Closed.—The board of education of Harlem has decided to close the public schools indefinitely on account of diphtheria, 20 cases of which have been reported to the board, with 6 deaths.

Re-Elected on Board of Health.—At the annual meeting of the State Board of Health, January 13, Dr. George W. Webster, Chicago, was re-elected president and Dr. James A. Egan, Springfield, secretary, each for a term of two years.

Scarlet Fever at Lake Forest.—On account of the prevalence of scarlet fever at Lake Forest, a temporary hospital has been opened for the care of those suffering from the disease. It has been decided that it will not be necessary to close the college at present.

Needs of State Charities.—The omnibus appropriation bill for the fifteen state charitable institutions calls for an expenditure of $5,005,890 for the two years beginning July 1. Of this amount $3,647,000 is required for ordinary expenses and $1,358,890 for special purposes, including new buildings at the Bartonville Hospital, an addition to the hospital at Watertown, a new building at the Anna Hospital and a hospital at the deaf and dumb institution.

Neely Made General Superintendent.—The president of the Board of County Commissioners of Cook County has appointed Dr. John R. Neely general superintendent of the county institutions at Dunning. This position is a new one. Its creation is a part of the work of reorganization which the president of the board has undertaken. Under it, the position of medical director is abolished, and the insane hospital, poor-house and consumptive hospital are all placed under the sole supervision of the general superintendent.

Chicago.

Keen Will Hold Clinic.—Dr. William W. Keen of Philadelphia will hold a surgical clinic at Mercy Hospital, Wednesday, January 28, from 9 to 11 a. m.

Alleged X-Ray Injuries.—John Bortoli has sued Lakeside Hospital for $25,000 on account of injuries alleged to have been received as a result of an *x*-ray examination in 1901.

1. See pages 219 and 220.

Hospital of St. Anthony de Padua.—The report of this institution for 1902 shows that 969 patients were treated during the year, with 96 deaths, 31 of which occurred within 72 hours after the patients' admission to the hospital.

Personal.—Drs. Nicholas Senn and Henry P. Newman are on a month's cruise in the West Indies.——It is announced that Dr. G. N. Stewart, professor of physiology in the medical department of Western Reserve University, Cleveland, has been appointed to succeed Dr. Jacques Loeb at the University of Chicago, and will enter on his duties April 1.

Deaths of the Week.—During the week ended January 17, 626 deaths were reported, 110 more than for the corresponding week of 1901, and one more than for the preceding week. The death-rate per annum was 17.31 per 1,000. Pneumonia caused 131 deaths; consumption, 55; heart disease, 49; Bright's disease, 34, and violence, 34. Bronchitis caused 27 deaths, and diphtheria, scarlet fever and whooping cough 9 each.

Dominant Pneumonia.—The health department, in its report for last week, sums up the pneumonia situation as follows:

Since the census year 1900 pneumonia has claimed more than one-eighth of all the victims of the Grisly Reaper in Chicago, one-third more than consumption and 46 per cent. more than all the other contagious and infectious diseases combined, including diphtheria, erysipelas, influenza, measles, puerperal fever, scarlet fever, smallpox, typhoid fever and whooping cough, the total of which deaths was 4,489, as compared with a total of 6,562 deaths from pneumonia.

During the first seventeen days of the current year, out of the total 1,436 deaths reported up to the close of record hours last Saturday, 299 were from pneumonia—or a little more than one-fifth of the total deaths from all causes. During the first seventeen days of last year 227 pneumonia deaths were reported, the figures showing an increase of nearly one-third (31.7 per cent.) this year over last.

How to Check Pneumonia.—The commissioner of health, after showing statistics of the increase of pneumonia, sums up the measures whereby this increase may be checked, as follows:

1. It is well known that pneumonia is a highly contagious disease, the cause of which is a micro-organism in the sputa of those suffering from the malady, and that it is contracted by inhaling this germ. Therefore, the same care should be taken to collect and destroy the sputa that is taken in pulmonary tuberculosis, or in diphtheria or influenza.
2. During the illness the greatest pains should be taken to prevent soiling bed-clothing, carpets or furniture with the sputa, and after the illness the patient's room should be thoroughly cleansed and ventilated.
3. The fact that the disease is most prevalent in the winter season, when people are most crowded together and live much of the time in badly ventilated apartments, makes obvious the necessity of thorough ventilation of houses, offices, factories, theaters, churches, passenger cars and other public places, in order that the air which must be breathed may be kept clean and free from infectious matter.
4. Laymen should be taught not to be afraid of a patient who has pneumonia, influenza or tuberculosis, but to be afraid of lack of cleanliness about him during his illness, of failure to enforce prophylactic measures and of close, badly-ventilated apartments during the season when these diseases most prevail.
5. Since pneumonia is most fatal at the extremes of life—the young and the aged—special care should be taken to guard children and old persons against exposure to the infection of those already suffering with the disease and against cold, privation and exposure to the weather, which are potent, predisposing causes.

INDIANA.

Malpractice Suit.—Dr. N. Howard Thompson, Wabash, is being sued for $10,000 by Fred Garrett on the charge of alleged negligence. By the explosion of a torpedo a piece of tin was forced into the cheek of Garrett, who says it was not removed properly.

Photographic Identification of Candidates.—The State Board of Medical Examination and Registration now requires that each applicant for examination shall hand in with his application, a photograph of himself. The reason for this new rule is that it will prevent substitution of one candidate for another in the examination. Some cases have been brought to the attention of the board, in which substitution is claimed to have been practiced.

Mortality and Morbidity.—The total deaths in the state during December was 2,634, 228 more than for November, the respective death rates per annum being 12.3 and 11.6 per 1,000. In November tuberculosis caused 309 deaths; in December, 319; typhoid fever, 146 and 91 respectively; pneumonia 181 and 267; influenza, 7 and 19; smallpox, 2 and 17. Smallpox was the most prevalent disease in both months, 441 cases being reported in November and 642 cases in December.

The Board's Good Work.—During the year 1902 the Board of Medical Examination and Registration issued 196 licenses; refused licenses to 14 applicants who failed to pass examination; revoked two licenses, one for drunkenness and the other for non-residence in the state, and brought and defended many lawsuits with the satisfactory result that it has won in every instance. The greater part of the suits against the board were brought by "magnetic physicians," "osteopaths" and other irregulars who had been refused licenses.

MARYLAND.

Personal.—Dr. W. Clement Claude, Annapolis, suffered last week from sepsis, arising from a scratch on his finger in an operation. He is said to be improving.

Hospital Incorporated.—Incorporation papers have been taken out for the "Union Hospital of Cecil County" at Elkton. Among the incorporators are Drs. Charles M. Ellis and Howard Bratton, Elkton, and George S. Dare, Rising Sun.

State Board's Annual Meeting.—The State Board of Health met at Baltimore, January 14, in annual session. Dr. William H. Welch was re-elected president; Dr. William R. Stokes, bacteriologist; Dr. C. W. G. Rohrer, assistant bacteriologist; W. D. B. Penniman, chemist, and C. W. Mitten, inspector.

Peninsula Hospital Report.—The fifth annual report of the Peninsula Hospital, Salisbury, shows 276 patients treated. Only 183 patients were residents of the County (Wicomico); 115 operations were performed. The buildings were strained to their utmost capacity to accommodate the demands. A new hospital building is in course of construction.

Smallpox.—Dr. John S. Fulton, secretary of the State Board of Health, reported two cases of smallpox at Stockton, two at Berlin, and two in Belair, also a number of "concealed cases" at Cumberland. The outbreak at Snow Hill has been subdued. A case of smallpox is reported at Kingsville, Baltimore County, in a man running on a boat between Baltimore and Southern Maryland, where the disease exists. Seven negro "suspects" gave themselves up to the police January 17. They had been employed on Little Gunpowder River, where one of their number became infected with smallpox. They were driven out of camp and their shanty burned. They immediately came to Baltimore and disappeared. One of the seven was found to have the disease and all were sent to the Detention Hospital.

Baltimore.

The Friedenwald Estate.—The personal property of the late Dr. Aaron Friedenwald is appraised at $76,071.36.

Vital Statistics.—The number of deaths for last week was 230. Measles is still very prevalent, 317 new cases being reported, but no deaths. There were 40 deaths from pneumonia.

Personal.—Dr. Morris Wiener celebrated his ninety-third birthday on January 15. He is a native of Berlin and a graduate of the University of Berlin.——Dr. George W. Dobbin has returned from a visit to Jamaica.

Alumni Meet.—A general meeting of alumni of the various schools of the University of Maryland was held, January 21, to devise ways and means of upbuilding the university and placing it on a modern footing as to government and endowment.

Hospital for Consumptives.—The annual meeting of the directors of the Hospital for Consumptives was held January 12. The hospital is located on an estate of 75 acres near Towson, the county seat of Baltimore County. It had during the year an average of 30 patients. It is dependent on the help of the city and state and also on private subscriptions. The woman's board connected with it contributed $1,100. Funds are needed for further cottages, also for a suitable entrance. Dr. Henry Barton Jacobs is to be the future president.

NEW YORK.

New York City.

Appeal for the Insane.—According to the report of the State Charities Aid Association, there is such urgent need for increased accommodations for the insane that the legislature is to be asked for an appropriation of at least $6,000,000.

Lectures on Spirit and Drug Addictions.—Dr. Thomas D. Crothers, Hartford, Conn., will deliver a course of lectures on alcoholism, morphinism and other drug manias, at the New York School of Clinical Medicine, 328 West Forty-second Street, on the first Tuesday of every month at 11 a. m. and 8 p. m. The profession is invited.

Hospital Closed.—The Williamsburg Hospital, which has been in existence for thirteen years, and which, prior to 1895, was known as the Brooklyn Throat Hospital, has been forced by the financial stress resulting from the unusually high price of coal and food, to close its doors. Its ward patients have been transferred to the Eastern District Hospital and the ambulance has been sold to the Bushwick Dispensary.

Mental Clinic.—The past few days in New York City have seen a novel clinic, namely, the utilization of the vast material of the Manhattan State Hospital by Dr. Adolph Meyer, the director of the State Pathological Institute. Eighty physicians from the various state hospitals for the insane gathered to study mental disease, and make themselves familiar with the latest developments in their special field of work.

Formalin Injections for Septicemia.—The daily papers have been stirred up for the past few days over the news that Dr. Barrows laid before the New York Obstetrical Society a treatment for septicemia, which had yielded an unexpectedly brilliant result in one case at Bellevue Hospital. The method consists in the intravenous injection of a 1 to 1,500 solution of formalin. We are not informed how the pernicious effect of the formalin on the blood corpuscles is prevented. Dr. Barrows tried this treatment on a second case, this time at St. Vincent's Hospital, January 16, and the same evening the method is said to have been tried at the Hahnemann Hospital. Dr. Barrows' first patient is said to be out of danger; his second case is improving, while the patient at the Hahnemann Hospital is reported to be slightly better. All three were looked on as practically hopeless cases before the formalin injection was tried.

Buffalo.

Personal.—Dr. Dennis J. Constantine has resigned as tenement-house inspector in the department of health.——The following additional appointments have been made to the staff of the Emergency Hospital; Drs. E. J. Meyer and E. M. Dooley, surgical department; Dr. L. G. Hanley, gynecology; Dr. J. J. Mooney, throat and ear; Dr. D. M. Keiser, ear, and Dr. B. H. Dagnett, genito-urinary.

Hospital Overcrowded.—Superintendent of the Poor Lafayette Long has reported to the County Board of Supervisors that the County Hospital was overcrowded, having 385 patients, whereas its capacity is limited to 350 patients. It is necessary to send 40 or 50 patients from the County Hospital to the Almshouse to sleep. The air space of the hospital is also inadequate, and is detrimental to the patients.

December Mortality.—The monthly report of the department of health for December shows an annual mortality rate of 16.31 per 1,000. The principal causes of death were pulmonary consumption, 46; diphtheria, 12; typhoid fever, 14; debility, 44; apoplexy, 23; valvular heart disease, 32; acute bronchitis, 20; pneumonia, 63; nephritis, 19; violence, 35. Total deaths for December were 503, as compared to 446 for December, 1901.

PENNSYLVANIA.

Hospital Bequest.—By the will of Susanna H. Thomas the Chester County Hospital receives $1,000.

Workingmen's Hospital Planned.—Plans are being matured for the erection in Pittsburg of a hospital, with branches throughout the city, particularly for the treatment of workingmen. At least $2,000,000 is needed for the project, and it is said that Andrew Carnegie has promised substantial aid.

Outbreak of Smallpox.—A recent outbreak of smallpox occurred at Bristol. The funds of the borough treasury are exhausted, more than $3,000 having been spent in fighting the disease. There is talk of a mass meeting to devise means for raising a fund to establish a municipal hospital and to fight the contagion. On January 1 Henry Althouse, Duquesne, died of what was diagnosed measles, but which proved to be smallpox. Three of his brothers have since died, on the same day, of smallpox, and a fourth is critically ill.

Re-Establishment of Emergency Fund Urged.—The associated health authorities of Pennsylvania are urging on the members of the legislature the pressing need of immediate re-establishment of the emergency fund to be used in coping with epidemics of contagious disease. It is especially needed in stamping out smallpox. Dr. Samuel T. Davis, chairman of the association's legislative committee, says that there is also crying need of legislation to protect streams from unnecessary pollution; that typhoid fever, because of such pollution, is costing the state thousands of lives and hundreds of thousands of dollars every year.

Philadelphia.

New Pavilions for Consumptives.—On January 16 ground was broken for the six new pavilions for consumptives to be erected at the Philadelphia Hospital.

Additions to St. Agnes' Hospital.—Improvements and additions are to be made to St. Agnes' Hospital at a cost of some $200,000. The new buildings will include a nurses' home, an operating room, a children's ward and an isolation ward.

Episcopal Hospital Improvements.—At its recent annual meeting the board of managers of the Protestant Episcopal Hospital decided to erect a dispensary building at a cost of $75,000. A ward for contagious diseases is also to be constructed.

Advocates Higher Standard.—Provost Harrison of the University of Pennsylvania, in connection with his review of the year's work of the institution, suggests, for promoting a higher standard of medical education, the appointment by the state of a board of examiners to pass the qualifications of those seeking admission to medical colleges.

Bequests and Donations.—A woman, who desires that her name shall not be made public, has given the University of Pennsylvania Hospital $10,000 for the founding of two free memorial beds.——Bequests of $1,000 each to the Jewish Hospital Association, the Jewish Foster Home, and the Jewish Maternity Association are made in the will of Jacob M. Engel, recently deceased.

Typhoid and Variola.—During the week ended January 18, 323 new cases of typhoid fever were reported. It is officially estimated that 2,000 cases are now under treatment in the city. Thirty-five new cases of smallpox, with two deaths, were reported for the week. The Masonic Home, which has 76 inmates, is quarantined because of the development of smallpox in an employe of the institution.

The Phipps Gift.—There is an obstacle to the immediate acceptance of the munificent gift of Henry Phipps of New York, a former partner of Andrew Carnegie, who proposed to establish in Philadelphia an institute for the study, treatment, and prevention of tuberculosis, and to endow it with $1,000,000 or more. There is a state law which prohibits the establishment or maintenance of any additional hospital in the built-up portions of cities. It is believed that the legislature will promptly repeal the law. The action of the legislature will probably determine whether or not Philadelphia will become the beneficiary of Mr. Phipps.

GENERAL.

Consolidation of Inebriety Journals.—The *Bulletin* of the American Medical Temperance Association and the *Journal of Inebriety* have been consolidated. The former was a quarterly medical review, the latter is the well-known monthly, the only publication devoted exclusively to liquor and drug diseases.

National Leper Colony at Hawaii.—The Senate special committee on Hawaiian affairs, in regard to leprosy, recommends the establishment of a National home for lepers of the United States on the island of Molokai and that the management be transferred to the U. S. Public Health and Marine-Hospital Service.

Manila General Hospital.—Mass meetings of citizens of Manila have been agitating the subject of a general hospital, of which there is need. The hospitals supported by voluntary contributions are not sufficient to meet the need and are not sure of support. The Philippine Commission was petitioned to take up the matter.

The Enno Sander Prize of the Association of Military Surgeons of the United States for 1903, will be awarded to the author of the best essay on "The Differential Diagnosis of Typhoid Fever in Its Earliest Stages." The board of award will consist of Dr. Austin Flint, New York; Col. Calvin DeWitt, U. S. A., and Dr. Victor C. Vaughan, Ann Arbor. Full information may be obtained from Major James Evelyn Pilcher, Carlisle, Pa., secretary.

A Philippine leper colony will be established on the island of Camalian, at a central point. The colony will be somewhat self-governing in its internal affairs, as some lepers are persons of high standing and ability, according to the *Manila American*. No marriages will be allowed, recent and mild cases will be separated from those that are severe and of long standing, relatives will be allowed to live near and see their kin at stated times, each person will be given a plot of ground and tools and it is planned that all vegetable produce necessary shall be raised on the island.

The Plague in Mexico.—During the first 15 days of January 107 deaths from plague occurred at Mazatlan, Mexico, and 106 houses have been burned. Money for relief and to furnish food and supplies is being contributed from California and other adjoining states. The Mexican congress held an extra session and that government is endeavoring to control the disease. The plague was rumored to be present in Mexico, Guadalajara and Sonora, Mexico, and Ensenada, Lower California, which reports were emphatically denied. Many towns in that part of Mexico are undergoing a most rigid sanitary overhauling, but there is no proof that the disease

has spread beyond Mazatlan. Quarantine is reported as rigid.

Proposed Army Hospital Corps Changes.—Surgeon-General O'Reiley has prepared a bill for the reorganization of the Army Hospital Corps, which has received the approval of Secretary Root and been presented to Congress. It provides for the Hospital Corps 300 first-class sergeants at $450 per annum, 300 sergeants at $300 per annum, 20 corporals at $240 per annum, 1,600 privates, first-class, at $216 per annum and 875 privates at $129 per annum, making total cost $770,400. By this arrangement the Hospital Corps will gain 95 men. The proposed classification of enlisted men is for the purpose of giving them titles more in accord with those used to designate the enlisted men in other branches of the service. Secretary Root's indorsement says General O'Reiley's proposed legislation will be a material benefit to an important branch of the military establishment.

The Senate Committee on Military Affairs has reported favorably on the bill providing for the promotion to next higher grade on retirement of those officers who served during the Civil War, but have been retired since Aug. 11, 1898. Among those affected by this bill, should it become a law, are Surgeons-General George M. Sternberg and William H. Forwood, who would consequently be promoted to the rank of major general. As this promotion was recommended to Congress by resolutions of the American Medical Association at Saratoga last year and the Committee on National Legislation was directed to secure this action by Congress, the committee earnestly requests each member of the Association to write at once to the committee on military affairs of both the House and Senate and also to his individual senator and congressman to vote for the passage of this measure.

The Bubonic Plague Conference.—The first conference of the U. S. Public Health and Marine-Hospital Service with state health officers was held January 19 at the office of the department in Washington. The meeting was called to order by Surgeon-General Wyman at 10:30 a. m. Those in attendance were:

California, Dr. Mathew Gardner; Connecticut, Dr. C. A. Lindsley; Colorado, Dr. H. R. Bull; Delaware, Dr. C. W. Cooper, Dr. Alex. Lowber; District of Columbia, Dr. Wm. C. Woodward; Indian Territory, Dr. M. R. Thompson; Iowa, Dr. T. L. Kennedy; Indiana, Dr. J. N. Hurty; Louisiana, Dr. Arthur Nolte; Maine, Dr. Charles D. Smith; Maryland, Dr. John S. Fulton; Minnesota, Dr. H. M. Bracken; New Jersey, Dr. Henry Mitchell; North Carolina, Dr. R. M. Lewis; Pennsylvania, Dr. Benj. Lee; Rhode Island, Dr. G. T. Swarts; South Carolina, Dr. T. G. Simons; Vermont, Dr. H. D. Holton; Virginia, Dr. P. A. Irving; New York, Dr. Daniel Lewis; Tennessee, Dr. J. A. Albright.

STATEMENT OF SURGEON-GENERAL WYMAN.

Dr. Wyman, in his introductory remarks, gave the object of the conference and stated that requests for conference had been received from and invitations to attend had been extended to the boards of health of the following states and territories: Colorado, Connecticut, Delaware, District of Columbia, Indiana, Iowa, Kentucky, Louisiana, California, Maine, Maryland, Minnesota, Mississippi, New York, New Jersey, North Carolina, Pennsylvania, Rhode Island, South Carolina, Tennessee, Vermont, Wisconsin and Virginia.

SURGEON GLENNAN'S MISSION.

Dr. Wyman referred to the New Haven Conference and the inspections made at that time. He told of the appointment of Surgeon Glennan to investigate matters in California. Surgeon Glennan, until a short time ago, was chief sanitary officer of the Public Health and Marine-Hospital Service in Cuba, having been the chief quarantine officer of that island and detailed on General Wood's staff during the American occupation. He was given instructions of which the following are a part:

As soon as possible after your inspection at San Diego, you will call upon His Excellency, Henry T. Gage, Governor of California, and present the following matter for his consideration, viz.: that there have been reported to the bureau 18 deaths from bubonic plague in San Francisco during the months of August (9) and September (9), and that from the reports received during these months and prior thereto, there are indications that three of the cases within the present year may have been brought into San Francisco from other places. This and the increased number of cases reported in San Francisco make it desirable that a careful inquiry be made with regard to several localities.

From former expressions, the bureau feels assured that the governor will approve of this measure, and may designate a representative to co-operate with a bureau representative in making these inquiries.

After consultation with the governor, you will report to the bureau as to any arrangements which may be effected.

In the opinion of the bureau this inquiry should be conducted in a deliberate and thorough manner, without haste or agitation, and the findings should be fortified by bacteriological examination. Furthermore, the inquiry should be so conducted that in the possible event of affirmative findings, nothing done during the inquiry would prove an embarrassment in the prolonged measures of extirpation which would be necessary; for it should be remembered that in the eradication of the disease the measures relating thereto, while they need not be of a character to disturb business or cause excitement among the people, must be very thorough, continuous, and of probable long duration.

An arrangement was effected, in accordance with the above instructions, by which Dr. Gardner, chief surgeon of the Southern Pacific Railroad, who, so far as could be ascertained by the bureau, had taken no attitude antagonistic to the recognition of plague and its eradication, together with Surgeon Glennan, should inspect the places named. Reports have been received of the investigations made at Oakland, Berkeley, Alameda, San Jose, Sacramento, Davisville, Stockton, Fresno and Bakersfield. No plague was found in said places.

Dr. Wyman further says: "These inspections are to be renewed from time to time as practicable. They had not yet been completed when I left Washington for New Orleans to attend the meeting of the American Public Health Association, and while there I determined to personally visit San Francisco to become acquainted, from personal observation, with the state of affairs."

DR. WYMAN'S PERSONAL VISIT.

After narrating the visits and inspections he personally made and the conferences held with officials from December 17 to 22, Dr. Wyman summed up as follows:

"In my opinion the resolutions of the state and provincial boards of health at New Haven have been productive of good, and I found a generally expressed desire to have the demands of the situation fully met. Governor Gage announced his intention of standing by his statement, but offered to assist in any way possible in the elimination of the disease which prevailed in Chinatown. A more important assurance was that given by Dr. Pardee, who seemed to fully realize the gravity of the situation and expressed his determination to leave nothing undone in the matter of giving aid and support to the necessary measures. Mayor Schmitz admitted to me in the presence of a witness that the disease was plague, and though he pointed out that he was not in harmony with his city board of health, he would nevertheless do everything possible to rid Chinatown of the disease and would give his best efforts in that direction.

"The city board of health, who deserve a great deal of credit for the work which they have done under trying circumstances, were informed that in all possible ways the service would assist them, that it was understood that the work going on in Chinatown was practically their (the city board's) work, and that while Governor Gage had offered, in illustration of his desire to assist in the elimination of the disease from Chinatown, the services of two inspectors to aid in that work, they were declined, inasmuch as it was deemed unnecessary in view of the inspectors already employed by the city board and the Public Health and Marine-Hospital Service, and I also informed the city board that in case of difficulty being experienced in obtaining means or persons for the prosecution of the work in Chinatown assistance would be rendered them by this service.

"I asked Dr. Williamson, the then president of the city board, his opinion as to the amount of plague which might be existing in Chinatown, and he expressed the opinion that it was not great. Of course, we both agreed that nevertheless it exists, and that careful and persistent inspection and sanitation would be requisite for an indefinite period, extending possibly over one or two years.

"As to the appearance of Chinatown itself, as observed during my two inspections, it was evident to myself that the great work which had been carried on there under Dr. Joseph H. White, now Assistant Surgeon-General, had been of permanent value, and it was evident, too, that the City Board of Health had been at work in Chinatown in the meantime. I tried to impress on all concerned that the work of attending to plague in Chinatown is properly the work of the City Board of Health, and that this service would aid both in a substantial manner and with counsel and advice. The activity of the state board in Chinatown, San Francisco, does not appear to be necessary unless there should be a laxity on the part of the city board.

THE PRESENT CONDITION.

"With regard to the present status, since my visit to San Francisco the new Governor, Dr. Pardee, has been installed, Dr. Williamson's term as president of the City Board of Health has expired and the mayor has appointed a new man in his place, Dr. Stinson, a temporary chairman has been elected, but a new president has not been chosen. It remains to be seen what the attitude of the City Board of Health under the

new régime will be, but if the mayor has an influence over his new appointees, and maintains the attitude toward the plague in Chinatown which he plainly expressed to me, I see no reason why the work should not be successfully pursued.

"In the meantime, from newspapers which have been sent me, I learn that the city council has appropriated money for the destruction of rats, and has also authorized the appointment by the Board of Health of an additional physician for duty in Chinatown, the City Board of Health then undertaking the sanitary surveillance of Chinatown and inspection of the sick, assisted at present by Assistant-Surgeon Currie, in charge of the laboratory of the service in San Francisco, who, with Mr. Wong, the Chinese interpreter, makes inspections twice a day of Chinatown, and similar inspection is made by another detailed officer of the service, Assistant-Surgeon Lloyd."

Dr. Wyman gave a report from Surgeon Glennan of the investigation of rats. From Nov. 8, 1902, to Jan. 12, 1903, 481 rats were examined, 446 being caught alive and 35 found dead. Of these, 4 live and 11 dead rats, or percentage of 0.9 and 31.4 respectively, were found to be infected with the pest.

THE DECISIONS OF THE CONFERENCE.

The conference adopted the following:

I. The presence of plague in California is established beyond debate by:

1. The investigations of Kellogg of the San Francisco Board of Health, Ryfkogel for the California State Board of Health, and Kinyoun for the United States Marine-Hospital Service.

2. By the later investigations of Pillsbury for the State Board of Health, and by those of J. White, M. White, Flint, Currie, Carmichael, Blue and Glennan for the United States Marine-Hospital Service.

3. By the findings of Flexner, Barker and Novy, composing a special committee acting under Federal authority.

4. By the findings of independent and disinterested investigators (supplied with materials from autopsies made at San Francisco, and working in San Francisco, Chicago, Boston, New York, Washington, Baltimore, Philadelphia and Ann Arbor).

5. By the occurrence of a case of human plague in Ann Arbor due to an accident in the manufacture of Haffkine's prophylactic fluid with a culture of plague bacillus obtained in California.

6. By the autopsy records of 90 cases of plague, now in the possession of the United States Marine-Hospital Service and of the San Francisco Board of Health, and published in part in the *Occidental Medical Times* of San Francisco. [NOTE.—See previous issues of THE JOURNAL for many of these.—ED.]

II. The presence of plague in any community where proper restrictions are not taken to prevent its spread is an injury to the best interests of that community. Such injury is in any case avoidable by the proper co-operation of all interests involved, commercial, professional and governmental. This conference regards the habitual publication of the actual facts relative to infectious disease and preventive procedures as the surest route to popular confidence, and is one of the means best adapted to minimize the injury liable to result from the presence of such diseases.

III. The present danger to California and to the United States lies primarily in the persistence, during nearly three years, of a definite nidus of plague infection in that part of San Francisco known as Chinatown; but the gravity of this circumstance is greatly increased by the gross neglect of official duty by the State Board of Health of California and the obstructive influence of the recent Governor of California, by the failure of the city government of San Francisco to support its city board of health, and by the obstacles opposed to the operations of the U. S. Public Health Service.

IV. The conference will consider the safety of the country sufficiently assured as soon as satisfied that a competent City Board of Health of San Francisco, and a competent State Board of Health, in co-operation with the U. S. Public Health Service, will proceed under definite, harmonious and effective laws and ordinances; that they are provided with ample funds; and that they are jointly and severally in the free exercise of their lawful powers.

V. The conference expresses its conviction that the U. S. Public Health Service has deserved well of the state of California and of the country, and that it would go far toward the restoration of popular confidence if the U. S. Public Health officials were admitted to the same relations with the State Board of Health as have been steadily maintained with the City Board of Health of San Francisco.

The praise of this conference and the gratitude of the city of San Francisco are due to Drs. John M. Williamson, Vincent P. Buckley, W. B. Lewitt, Rudolph W. Baum, Louis Bazett, and Dr. McCurtley, of the City Board of Health of San Francisco. These men possess the unreserved confidence of the executive health officers of the country.

A vote of thanks is extended to General Wyman and a vote of confidence in the Public Health and Marine-Hospital Service.

CANADA.

Personal.—Dr. L. W. Cook, Truro, Nova Scotia, has gone to Newfoundland to take the practice of Dr. Herbert Smith of Buren, who will take a post-graduate course abroad.

Proposed Children's Hospital, Montreal.—It has been decided that this hospital shall be an adjunct to the Montreal General, the Royal Victoria and other hospitals of the city. This will relieve the over-taxed general hospitals and allow them to extend their spheres of usefulness, more particularly to those suffering from acute diseases.

Quebec Bad School Conditions.—At the regular meeting, January 14, of the St. Francis Medical Association, which comprises physicians of the eastern townships of the province of Quebec, Dr. Stevenson, inspector of public buildings, Coaticook, proposed a memorial to the provincial government protesting against certain prevailing conditions in the Protestant elementary schools, viz.: 1, pupils are required to take up too many subjects and their health suffers; 2, a very bad system of ventilation prevails in nearly all public school buildings he has visited in the eastern townships.

Montreal's health report for November showed 168 new cases of contagious diseases, with 26 deaths; 34 of diphtheria, with 4 deaths; 36 of scarlet fever, with 6 deaths; 28 of typhoid fever, with 8 deaths; 55 of measles, with 4 deaths; 2 of whooping cough, both fatal; 9 of chicken-pox and 3 of smallpox, no deaths. At the scarlatina and diphtheria hospital 29 patients were admitted, of whom 20 had scarlet fever and 9 diphtheria; 7 of these died. The district physicians made 606 primary and 63 secondary vaccinations. The number of deaths in Montreal during November was 484.

Vaccination by the Laity in New Brunswick.—The law in this province requires that before children are admitted to any public school they must show certificates of successful vaccination within three years preceding. Certain boards of health have required that these certificates must be signed by physicians, but the attorney-general has recently ruled that a certificate of a parent or guardian, verified by a solemn declaration, will be sufficient. This is considered to be important because it has been the habit in country sections of the province for parents to procure vaccine points and vaccinate their children themselves.

FOREIGN.

German Venereal Prophylaxis.—The first congress of the German Society for the Prevention of the Spread of Venereal Diseases will convene at Berlin March 8 to 10, 1903.

Plague Extinct at Odessa.—The *St. Petersburg Med. Woch.* announces that no new suspicious cases have occurred at Odessa since October, and the city is now declared free of the plague.

Nothnagel a Senator for Life.—Prof. Hermann Nothnagel, director of the first medical clinic at Vienna, has been appointed a member for life of the upper house of the Austrian parliament.

Germ of Hydrophobia.—Professor Sormani of the University of Pavia, Rome, is reported in the daily papers to have discovered the hydrophobia microbe, which has so long eluded absolute demonstration.

Abuse of Ether in Russia.—Our German exchanges mention that the custom of using ether for a beverage is spreading from Russia into eastern Prussia. At a recent wedding feast at Trossno a large quantity had been provided, and as it was being poured it exploded and killed 7 and injured 14 persons.

Posner a Professor.—Dr. Carl Posner, one of the proprietors and editors of the *Berliner klin. Wochenschrift*, and of the *Jahresberichte der Fortschritte der Medicin*, has been raised from the rank of privat docent to that of professor at Berlin. He is one of the leading minds in the medical press of Europe.

Scientific Instruction of Italian Police.—Professor Ottolenghi has been delivering a course of lectures with demonstrations to the police officials at Rome and Siena to instruct them in scientific means of identifying criminals, determining the nature of the crimes and other points of importance in their service.

Bureau of Medical Information at Paris.—The city council has appropriated $750 for the equipment of a bureau of information in regard to scientific matters, for the benefit of strangers. It is to be installed in some public building, the Sorbonne or the Faculté de Médecine, and officials speaking the current foreign languages will be in charge.

Individual Communion Cups.—The presidents of the medical societies in Denmark and all the high medical functionaries signed a declaration published Dec. 28, 1902, protesting against the use of the common communion cup as fraught with danger from the point of view of contagion. They recommend a special chalice with individual cups, filled in turn by a special mechanism.

Chair of Experimental Therapy Founded at Berlin.—The privat docent A. Wassermann has been appointed professor of experimental therapy, and will lecture in the Institute for Infectious Diseases, with which he has been connected as Koch's assistant since 1891. His researches on the biologic blood test,

serumtherapy and immunity have carried his name far and wide. He is now in his thirty-eighth year.

Donath the Recipient of the Craig Colony Prize.—The prize offered by the Craig Colony, Sonyea, N. Y., for the best original work on the pathology and treatment of epilepsy, has been awarded to the privat docent of neurology at Budapest, Dr. Julius Donath. The title of his work is "The Importance of Cholin in Epilepsy." Last year an Italian, Dr. C. Ceni, received the prize for his research on the serum treatment of epilepsy.

Jubilee of the Muenchener Med. Wochenschrift.—Our Munich exchange is to be congratulated on attaining its fiftieth year of efficient and dignified service to science and to the profession. The new volume is to be opened by works from the pens of its ten founders and proprietors, v. Angerer, Bäumler, Bollinger, Curschmann, v. Leube, Merkel, v. Michel, Penzoldt, v. Ranke and v. Winckel. The new heading for the title page portrays the physician in his study and at the bedside.

Increase of Ankylostomiasis in Germany.—In the Bochum district the number of cases of ankylostomiasis has increased from 286 in 1900 to 1,029 cases in 1901, with 5 deaths. Attempts to disinfect the running water in the mines have hitherto proved fruitless or have obstructed the pipes. The addition of a solution of copper vitriol seems to be the last resort, but is expensive. All sanitary precautions meet with passive resistance on the part of the miners, and the local medical press regards the outlook with apprehension.

Government Insurance Against Industrial Accidents in Sweden.—A bill has passed the Swedish parliament and been signed by the king which provides for insurance against accidents incurred in wage-earning work. The first expense, treatment, etc., is borne by the employer. After the sixtieth day an indemnity of 27 cents is paid daily during convalescence. Later the indemnity for complete loss of working capacity is 300 kronen, about $81. An official insurance bureau is to be organized to have charge of the details. Railroads, tram lines and mines are included in the list.

Centennial of the Dorpat University.—On the occasion of the celebration of its centennial the Russian university at Jurjew, better known by its former Polish name of Dorpat, conferred honorary degrees on 20 prominent medical men. The list of 5 Russian names includes, as a matter of course, Pawlow and Bechterew. Among the foreigners are E. v. Bergmann and Naunyn, who were formerly professors at Dorpat; Ziegler, Baumgarten, Waldeyer, Flechsig, Gegenbaur and v. Köllicker, in Germany; Brouardel and Cornil, in France; Lord Kelvin and Horsley, in England; G. Rezius of Stockholm, and Ramon y Cajal of Madrid. A large number of important works were also dedicated to the university on the occasion, among them Truhart's work on the pathology of the pancreas.

Suggestion for Legislation to Favor Large Families.—A French army officer and assistant director of the military School, M. Toutée, proposes a new means of endeavoring to raise the birth rate in France. He suggests that the laws of inheritance be modified so that the estate be divided in equal parts, to be awarded to children and grandchildren alike. A son of the family, for instance, under such a law, could claim not only his own share, but also an equal amount for each of his children. An only child could inherit only half of the property, the balance going to the heirs after him. He thinks that legislation along these lines would accomplish its purpose automatically and lead to the rearing of large families by the cupidity of the parents, sons and daughters of capitalists.

Opening for Physicians at Peru.—The American consul, C. V. Herdliske at Callao, the port for Lima, writes in reply to an inqury as to the prospects for physicians in Peru, that the candidate who applies for leave to practice must pass an examination in Spanish before the National Medical Board, regardless of the degrees he has obtained elsewhere. "When he has passed this examination the prospects of success seem very good. There is a large English and American colony at Lima and Callao, and the Peruvians seem to have special confidence in the American, English, German or French physicians who have settled there." The South American medical schools, however, graduate a large number of doctors every year. At Buenos Ayres alone 1,964 matriculated at the university medical school in 1901.

Third International Congress of Thalassotherapy.—The Biarritz Association has organized six international congresses of hydrology, climatology and geology and two of marine therapy. It now announces that a third international congress of marine thalassotherapy will be held at Madrid on the occasion of the approaching International Medical Congress, the date April 19 to 21. Addresses are prepared by A. Robin and M. Binet of Paris on the "Influence of a Stay at the Seashore on the Inner Phenomena of Nutrition," by Lalesque of Arcachon on the "Effects of the 'Marine Treatment from the Standpoint of the Generalization of Tuberculosis." and by Huchard and Feissinger on the "Influence of the Seashore on the Cardiovascular Apparatus." The membership fee is 10 francs, or $2.50, to be remitted to M. Raynaud, pharmacist at Biarritz. The secretary for the foreign department is Dr. Seguel, 68 boulevard Malesherbes, Paris.

Jubilee of El Siglo Medico.—Our Madrid exchange, in entering on its fiftieth year with the current number, reviews the history of medicine in Spain during the half century, and cites many names of at least national fame. It describes the great change that has come over the profession of late years, dividing it into two widely separated classes, the "high speciality," the medical aristocracy, with successes and emoluments hitherto unparalleled, and the lowly members of the profession contending at every step with enemies and abuses, the machinations of charlatans, sick benefit societies, pseudo-charitable organizations, etc., with poverty and despair threatening to engulf them. "The 'promised land' is still far ahead, but with co-operation and good counsel the profession will win it at last. In this campaign the medical press must play an important rôle, as wise leadership was never needed so much as now, and the achievements and experiences of the past will spur it on to higher ideals, a continuous growth and evolution to conform to the necessities of the hour."

Prizes Offered by the Paris Academy of Medicine.—We give below the list of endowed prizes which the *Académie de Médecine* of Paris opens to the competition of the world. The lists are closed the end of February for the current year. All works must be in French or Latin. The academy had for distribution in 1898 84,000 francs, the total for 42 prizes, and in 1902 62,000 francs for 38 prizes, exclusive of the Audiffred prize. This year the prize endowed by the surplus left after the XIII. International Medical Congress of Medicine, at Paris, will be placed in the hands of the executive committee of the approaching International Medical Congress at Madrid, to be awarded in a single prize.

The academy prize of 1,000 francs will be awarded in 1903 for the best work on "Means of determining the eliminating power of the kidney"; in 1904, on "Cirrhosis of the liver; clinical and experimental"; in 1905, on "Oxydases in pathology." Alvarenga, 800 francs, annual, for best work in any branch of medicine. Capuron, 1,000 francs, 1903, "Action of saline waters in general on the digestion"; 1904, "Applications of radiography to obstetrics"; 1905, "Complications of pregnancy due to lesions of tubes and appendix." Civrieux, 800 francs, 1903. "Cerebral troubles in sclerosis in patches"; 1904, "Rôle of syphilis in affections of the encephalus"; 1905, "Deliriums in epileptics." Daudet, 1,000 francs, 1903, "General medications in treatment of cancer"; 1904, "Surgical treatment of neoplasms of large intestine with exception of rectum"; 1905, "Epitheliomata of the neck of branchial origin." Falret, 700 francs, 1904, "Neurasthenia, pathogenesis and treatment." Lefèvre, 1,800 francs, 1905, "Melancholia." Louis, 3,000 francs, 1904, "Serum treatment of typhoid fever." Mège, 900 francs, 1904, "Etiology and pathogenesis of arteriosclerosis." Orfila, 6,000 francs, 1904, "Alkaloids of belladonna, hyoscyamus and datura." Portal, 600 francs, 1903, "Pathologic anatomy of salpingitis in its relation to the producing causes"; 1904, "Comparative hematologic study of variola and vaccine"; 1905, "Pathologic anatomy and pathogenesis of cancer." Pourat, 700 francs, 1903, "Microbian secretions and their physiologic action in the genesis of diseases"; 1904, "Circulation of blood in the lungs"; 1905, "Effects of mechanical actions on the morphology of the locomotor apparatus."

All articles competing for the above prizes must be anonymous and accompanied by the name and address of the author in a sealed envelope. In addition to these prizes the list below is open to MSS. or printed works:

Amussat, 1,000 francs, 1905, for best work or researches based simultaneously on anatomy and experimentation, which has realized or prepared the way for the most important progress in surgical therapeutics. Apostoli, 600 francs, annual, for best work on electrotherapy. Argenteuil, 6,800 francs, 1905, for most important progress during preceding six years in treatment of strictures of the urethra, or for best work on treatment of other affections of urinary passages. Audiffred, income of 24,000 francs, for the discovery before 1921 of a sovereign remedy for tuberculosis. Baillarger, 2,000 francs, 1904, for best work on treatment of mental diseases and organization of insane asylums. Barbier, 2,000, annual, for complete means of cure for hitherto reputed incurable affections, such as cancer, hydrophobia, epilepsy, scrofula, typhus, cholera morbus, etc. This prize may be divided. Boullard, 1,200 francs, 1904, for best work or best curative results in mental affections. Bourceret, 1,200, annual, for best work on circulation of blood. Bulsson, 10,500 francs, 1904, for discoveries having for result the cure of maladies hitherto reputed incurable. Duplerris, 2,300 francs, 1904, for best work in anesthesia or on affections of urinary passages. Chevillon, 1,500, annual, for best work on treatment of cancerous affections. Clarens, 400, annual, for best work on hygiene. Desportes, 1,300 francs, annual, for best work on practical medical therapeutics and on practical and therapeutic natural history. Godard, 1,000, annual, best monograph on internal and ex-

ternal pathology. Guzmann, income of 1,328 francs, for really effective treatment of the most common forms of organic heart disease, or prize of same amount for best work in this line. T. Herpin, 3,000 francs, annual, for best work on epilepsy and nervous diseases. Itard, 2,400 francs, 1903, for best book of practical medicine or applied therapeutics, published at least two years previously. Jacquemier, 1,700 francs, 1904, for work on some obstetric subject that has realized important progress. Labordie, 5,000 francs, annual, for author who has notably advanced the science of surgery. Larrey, 500, annual, for best work on medical statistics. Lefort, 300, 1903, for chemical study of mineral and drinking waters. Lorquet, 300, annual, for best work on mental diseases. Meynot, 2,600 francs, annual, for best work on eye and ear affections, or, exceptionally, for some great medical discovery. Monbinne, 1,500, annual, for scientific mission, medical, surgical or veterinary. Nativelle, 300, annual, for extraction of some active, definite principle of some medicament, hitherto unisolated. Perron, 3,800, 1905, for monograph "most useful to the progress of medicine." Ricord, 600, 1903 and 1905, for best work appearing in the two preceding years on venereal diseases. Saint-Lager, 1,500, 1904, for experimental reproduction of endemic goiter. Saintour, 4,400, 1904, for best work, MSS. or printed, on any branch of medicine. Stanski, 1,400, 1904, for research on epidemic diseases. Tremblay, 7,200, 1903, for best memoir on affections of the urinary passages, catarrh of the bladder and affections of the prostate in particular. Vernois, 700, annual, for best work on hygiene.

A franc equals 19½ cents.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

RUHEMANN'S URIC ACID TEST.

ST. LOUIS, Jan. 1, 1903.

To the Editor:—1. Will you please inform me where I can find the description of Ruhemann's test for uric acid; 2, also the latest theory on origin of basophile bodies in red blood corpuscles?

A.—E. M.

ANS.—Ruhemann's test was published in the *Berliner klinische Wochenschrift*, Jan. 20, 1902, and an abstract of his paper was given in THE JOURNAL, March 1, p. 620, vol. xxxviii. 2. We think the majority of opinion is that these bodies, occurring as they do in lead poisoning, etc., are indications of degenerative processes, though some may hold the contrary.

DISCUSSION ON EPILEPSY.

ST. PETER, MINN., Jan. 19, 1903.

To the Editor:—On page 161 of THE JOURNAL for Jan. 17, 1903, in the last line of my remarks in closing the discussion on the Symposium on Epilepsy, in some way the word "human" has been substituted for the word "known" completely changing the meaning of the sentence. H. A. TOMLINSON.

ARIZONA, OKLAHOMA AND INDIAN TERRITORY PRACTICE.

Jan. 13, 1903.

To the Editor:—Kindly inform me through THE JOURNAL what the requirements of Arizona, Oklahoma and Indian Territory are, also the names of the secretaries of each of the above states, with addresses. J. C. B.

ANS.—In Arizona an examination is required, the secretary of the board is Dr. Wm. Duffield, Phœnix. In Oklahoma, registration is made on a diploma approved by the board, the president is Dr. E. E. Cowdrick, Enid, to whom application should be made. In Indian Territory the laws differ in the jurisdictions of the various nations and we can not give the data required. We hope in a very short time to publish a revision of the pamphlet issued a year ago, giving the laws of all the states and territories corrected to the first of the year. Copies may be had for 25 cents.

GONORRHEA CURED OR LATENT?

January 18, 1903.

To the Editor:—I wish your advice on the following case: Patient contracted specific urethritis (for first time) three and one-half years ago. He used protargol (1 to 2 per cent. solution) locally for two months and a 0.5 per cent. solution of copper sulphate. He was apparently cured for two years, although there was a constant moisture of the urethra, but never during that time a discharge. For one year there has been a clear and sometimes milky discharge, but not profuse. In the morning a minute drop can be squeezed from the urethra. There are practically no subjective symptoms. The patient has phosphaturia and has noticed that the discharge is more perceptible when the urine is loaded with phosphates. Six bacteriologic examinations, two of the urine, two of the seminal fluid and two of the discharge, by different bacteriologists, were negative for gonococci. Two urethroscopic examinations show no granular urethritis. Irrigations of permanganate of potash and weak silver nitrate solutions gave no apparent benefit. He never had any complication and positively has had no secondary infection. The patient wishes to marry within a few months and may have to. Would you advise him to marry without danger of infection? What treatment would you advise?

ANS.—It is impossible to say whether there is latent gonorrhea. Any one who advises as to that point takes on himself a very grave responsibility. We should advise more careful examinations and great caution as to the advice you give him. We can not do better than to call your attention to page 239 of this issue, where Drs. Anthony and Campbell speak on this point.

Correspondence.

Method of Reducing Strength of Solutions.

BALTIMORE, Jan. 16, 1903.

To the Editor:—By accident, a few years ago, I discovered this simple but accurate method of reducing the strength of solutions, and finding it so useful in my special line, viz., throat and nose work, I hope you will publish it and that it may prove of value to some fellow practitioner. It is as follows:

Of the original solution take a number of parts equal to the percentage to which it is desired to reduce and thereto add a sufficient number of parts of the diluting substance (as of water) so that the sum of the two will be equal to the percentage of the original solution.

As, for example, to reduce a 10 per cent. solution to a 4 per cent. solution: Take 4 parts of the 10 per cent. solution and add thereto 6 parts of water, and so obtain the desired 4 per cent. solution. If I need only a small quantity of a solution I use a medicine dropper or pipette and measure by drops. To reduce a 5 per cent. solution to 1½ per cent. solution, simply double the 5 and the 1½ and I have 10 and 3, and taking 3 drops of the 5 per cent. solution and adding 7 drops of water thereto I have a 1½ per cent. solution.

HUGHLETT HARDCASTLE.

Dr. Croftan's Iodin Starch Test for Adrenal Extract.

CINCINNATI, Jan. 15, 1903.

To the Editor:—In a recent number of THE JOURNAL (Jan. 10, 1903, p. 91) Dr. Alfred C. Croftan has published a series of tests said to be characteristic of adrenal tissue or extract, by means of which he proposes to differentiate adrenal tissue and hypernephromata.

One of the most striking and constant of these tests is described as "The Power to Decolorize Iodin-Starch Solution." The test is made in the following manner:

> Equal portions of starch solution having been distributed in several test tubes, hypernephroma extract was added to one-half of them, and then one drop of an alcoholic iodin solution was added to each. Those tubes that contained no hypernephroma extract immediately turned blue and remained blue, whereas those tubes that contained hypernephroma extract turned blue for an instant only and became immediately decolorized.

It seemed to the writer to be important that this test be applied to other extracts, and the following extracts of tissues which were at hand were subjected to this test. They all gave the Croftan reaction in all its characteristics; that is, the blue iodin starch solution was decolorized.

The following is a list of extracts tested: Thyroid (P. D. & Co.), thymus (Armour), extract of meat (Liebig), pepsin (Fairchild), and pancreatic extract (Dry).

S. P. KRAMER, M.D.

Marriages.

ROBERT B. LEES, M.D., to Miss Clementine Denhart, both of White, S. D.

ALBERT W. MOORE, M.D., to Miss Helen Hough, both of Bristol, Ill., January 1.

STELLA B. JONES, M.D., to H. C. Nelson, both of Oshkosh, Wis., Dec. 11, 1902.

WILLIAM E. WELLS, M.D., to Miss Cora Stubbs, both of Tampa, Fla., January 7.

FRENCH A. SMITH, M.D., to Miss Bertha P. McCall, both of Mullins, S. C., January 7.

LOUIS STORROW GREEN, M.D., to Miss Louise Packwood Burke, both of Alexandria, Va., January 7.

VINCENT J. COHENOUR, M.D., Joliet, Ill., to Miss Myrtle Belle Harbour of Rosemond, Ill., January 7.

E. S. ARNOLD, M.D., Everett, Mo., to Miss Emma Watts of Belton, Mo., at Harrisonville, Mo., January 6.

FREDERICK RUSSELL HUXLEY, M.D., Faribault, Minn., to Miss Ada Daniels of Minneapolis, Minn., January 8.

REYNALDO J. FITZGERALD, M.D., Minneapolis, Minn., to Miss Eleanor Bradley of Aberdeen, S. D., January 8.

CLAUDE G. BURGESS, M.D., Northville, Mich., to Miss Sarah Eliza Penniman of Plymouth, Mich., January 7.

STEPHEN VICTOR BALDERSTON, M.D., Evanston, Ill., to Miss Elizabeth Thompson of Old Point Comfort, Va., January 5.

Deaths.

William Weir Hester, M.D. Louisville, Ky., 1858; Jefferson Medical College, Philadelphia, 1873; lieutenant-colonel of the Forty-Eighth Kentucky Volunteer Mounted Infantry in the Civil War; a member of the American Medical Association; assistant physician at the State Hospital for the Insane, Indianapolis, and at the Illinois Southern Hospital for the Insane, Anna; since 1890 a practitioner of Chicago, died at his home in that city, July 18, 1902, aged 67.

Oliver W. Weeks, M.D. Cincinnati College of Medicine and Surgery, 1875, a veteran of the Civil War, formerly surgeon-general of the Grand Army of the Republic; sometime president of the Marion County (Ohio) Medical Society, a member of, and earnest worker in the Ohio State Medical Society and the American Medical Association, died at his home in Marion, Ohio, from pneumonia, January 11, aged 61.

Robert S. Wallis, M.D. Missouri Medical College, St. Louis, 1854; Jefferson Medical College, Philadelphia, 1861; surgeon in Confederate Army during the Civil War; died suddenly on a train at Palestine, Texas, while en route to his home in Rockdale, Texas.

S. Evaline Bailey, M.D. State University of Iowa, College of Homeopathic Medicine, Iowa City, 1883, died at her home in San Diego, Cal., Dec. 30, 1902, two days after an accidental fall, in which her hip was fractured, aged 55.

Samuel Alexander Work, M.D. University of Michigan, Ann Arbor, 1883, died from heart disease and dropsy at his home in Vandalia, Mich., January 6, aged 60. He was a member of the American Medical Association.

William Mote, M.D. Medical College of Ohio, Cincinnati, 1856, died suddenly from heart disease at his home at Hog Point, north of Lafayette, Ind., January 9, aged about 70.

Watkins Warren, M.D. Medical College of Virginia, Richmond, 1860, a retired physician of Mount Vernon, Ill., died at Thomasville, Ga., January 2, after an illness of a week.

Bushrod W. James, M.D. Hahnemann Medical College, Philadelphia, 1857, died at his residence in Philadelphia, January 6, from an anemia, after a long illness, aged 66.

N. L. Van Sandt, M.D. Eclectic Medical Institute, Cincinnati, 1850, died at his home in Clarinda, Iowa, January 5, from paralysis, after an invalidism of a year, aged 77.

W. Frank Ross, M.D. College of Physicians and Surgeons, Baltimore, 1881, died at his home in Knoxville from Bright's disease, January 6, after a brief illness, aged 63.

Francis M. Davis, M.D. University of Maryland, Baltimore, 1856, died at his home in Bedington, W. Va., Dec. 28, 1902, from dropsy, after a long illness, aged 70.

William W. Misner, M.D. Hahnemann Medical College, Chicago, 1883, died at Tacoma, Wash., January 3, two weeks after an operation for appendicitis, aged 48.

George E. Shuey, M.D. Medical College of Indiana, Indianapolis, 1882, was burned to death, January 8, at his boarding place in Medora, Ind., aged about 40.

William G. Thomas, M.R.C.P. England, 1868, died suddenly at his home in Waukesha, Wis., presumably from heart disease, January 10, aged 65.

Charles W. Sibley, M.D. Bellevue Hospital Medical College, New York, 1877, died at his home in Fairfield, Ill., from Bright's disease, January 13.

James H. Auld, M.D. Rush Medical College, Chicago, 1883, died from pneumonia at his home in Lincoln, Neb., January 6, after an illness of ten days.

Rachel F. Reid, M.D. Ohio Eclectic Medical College, 1857, died at his home in Pasadena, Cal., from pneumonia, after an illness of six days, aged 77.

James E. Helm, M.D. Louisville Medical College, 1882, died at his home in Louisville, Ky., January 12, from bronchitis, after a long illness.

David H. Reed, M.D. University of Buffalo, N. Y., 1883, died at his home in Remsen, N. Y., January 9, after a long illness, aged 48.

Cornelius S. Smith, M.D. Pennsylvania Medical College, Philadelphia, 1850, died at Fort Wayne, Ind., Dec. 29, 1902, aged 82.

William H. Bowles, M.D., 1868, died at his home in Lane's Prairie, Mo., January 5, from pneumonia, after a short illness, aged 85.

William J. O'Connell, M.D., mayor of Mingo Junction, Ohio, died suddenly at his home in that place, January 6.

Honore Noel, M.D., one of the oldest practitioners of Maine, died at his home in Waterville, January 11, aged 74.

Alexander F. Bueren, M.D. University of Louisville (Ky.), 1874, died, January 7, at his home in Louisville, aged 53.

Eugene White, M.D. University of Tennessee, Nashville, died at his home near Lebanon, Tenn., aged 36.

James C. Fleming, M.D. Cleveland Medical College, 1867, died recently at his home in Carlisle, Ohio.

John N. Lowe, M.D. New York University, 1862, died at his home in Milford, N. J., aged 78.

Deaths Abroad.

Dr. F. Occhini, professor of clinical medicine at Rome.——**Dr. Max Schede,** professor of surgery at Bonn, in his 60th year.——**Dr. Zaayer,** professor of anatomy at Leyden, and author of various works on the architecture of the bones, "Scaphocephalous Skulls," "High Origin of Arteria Profunda Femoris," etc.——**Dr. O. Rapin,** professor of obstetrics at Lausanne.——**Dr. M. G. Aragon,** professor of hygiene, zootechnics, etc., at Mexico, Dec. 12, 1902, aged 66. To his efforts Mexico owes the establishment of veterinary medicine on a scientific basis and the foundation of a special journal.——**Dr. I. Herrnheiser,** privat docent of ophthalmology at Prague, and editor of the *Prager Med. Woch.*

Dr. Hans Rabl, a prominent physician of Vienna, one of the circle of medical men during Vienna's most brilliant period. He was born in 1830, and devoted many years to practice in the watering place, Bad Hall, which became the center of medical and surgical achievement in that part of Europe. He was the first to perform a successful ovariotomy in either Germany or Austria, and from his wide experience with scrofula and lues published a number of important works. Among the latest are some on the influence of the dwelling place on the morbidity and mortality of tuberculosis.

Book Notices.

THE INTERNATIONAL TEXT-BOOK OF SURGERY. In Two Volumes. By American and British Authors. Edited by J. Collins Warren, M.D., LL.D., F.R.C.S. (Hon.), Professor of Surgery, Harvard Medical School; and A. Pearce Gould, M. S., F.R.C.S., of London, England. Second Edition, Thoroughly Revised and Enlarged. Vol. I. General and Operative Surgery. Royal Octavo of 965 pages, with 461 Illustrations, and 9 Full-paged Colored Lithographic Plates. Vol. II. Special or Regional Surgery. Royal Octavo of 1122 Pages, with 499 Illustrations, and 8 Full-Paged Colored Lithographic Plates. Cloth. Price, $5.00 net. Philadelphia and London: W. B. Saunders & Co. 1902.

The first edition of this work appeared two years ago, and was fully reviewed in these columns.

In this, the second edition, we notice a number of changes and additions, which add considerably to the value of the work. Vol. I has been enlarged by the addition of 18 new pages and several new illustrations. Among the additions to this volume may be mentioned the use of pure carbolic-acid and alcohol in the disinfection of wounds and septic cavities, the carbolic acid treatment of tetanus, the use of gelatin in the treatment of certain hemorrhages, the modern treatment of wounds of the head, etc. Intraspinal cocainization is described and properly condemned, except, perhaps, under special conditions. The chapter on diseases of the lymph system has been entirely rewritten and materially improved. Attention is particularly directed to the recent work done on splenic anemia. We fail to find any reference to cytodiagnosis, which has opened up

such an interesting field in the diagnosis of diseases of the serous membranes. Vol. II has been enlarged by the addition of 55 pages. Of the new matter may be mentioned Brophy's operation for cleft-palate and Edebohl's decortication of the kidneys in Bright's disease, but the statement that "even patients far advanced in the disease, with cardiac hypertrophy and uremic symptoms have been much benefited," should be accepted with considerable hesitation as this is yet far from being proven. The use of the *x*-ray in the treatment of diseases of the skin has been very well set forth, also the peculiarities of the so-called *x*-ray burns. We fail to find any mention of Keen's method of laryngectomy for carcinoma of the larynx; also of Abbe String and Dunham's excellent and ingenious modification of this operation in the treatment of strictures of the esophagus. Under surgery of the stomach and intestines there is no reference to Finney's operation on the pylorus, nor to the Connell suture, etc. On the whole, however, the subjects have been brought well down to date, and the volumes make one of the best works on surgery we have.

NOTHNAGEL'S PRACTICE OF MEDICINE: American Edition. Diseases of the Bronchi. By Dr. F. A. Hoffmann, of Leipsic. Diseases of the Pleura. By Dr. O. Rosenbach, of Berlin. Pneumonia. By Dr. F. Aufrecht, of Magdeburg. Edited, with Additions, by John H. Musser, M.D., Professor of Clinical Medicine, University of Pennsylvania. Seven Full-Page Colored Lithographic Plates. Pp. 1030. Cloth. Price, $5.00 net. Philadelphia and London: W. B. Saunders & Co. 1902.

This, the fourth, volume of the American edition of Nothnagel's Practice keeps up the reputation which the previous volumes of this excellent work have made. It contains exhaustive monographs on the bronchi and emphysema and atelectasis by Hoffmann of Leipsic; in inflammation of the lungs by Aufrecht of Magdeburg-Altstadt; and on diseases of the pleura by Rosenbach of Breslau. It is edited by Dr. John H. Musser of Philadelphia. These monographs in the original hold an enviable place in German medical literature, each one being exhaustive, complete and authoritative and written by men specially fitted for the work. But the American edition is not only a reproduction in English, it is all of this and more, for the American editor has added much of value not included in the original and he has brought every part thoroughly up to date. This includes recent additions to our knowledge of the anatomy and physiology of the bronchi; on the pathology, bacteriology and treatment of bronchitis, etc. In fact, there are evidences all through the book showing that the editor has made use of the most recent literature. While the book is a large one—over a thousand pages—there is no evidence of padding; on the other hand, it is concisely written, and the additions and comments made by the editor are especially clear, short and to the point. The bibliography following each part is apparently complete; it is certainly valuable. The literature up to and including the first half of the current year, 1902, is recorded. Altogether the book is without doubt the most scientific, complete and up-to-date work in the English language on the diseases to which it is devoted.
